of whether to operate or not in cases showing evidence of early cirrhosis was answered by Dr Hutcheson's patient, who was living twelve years after operation, and by a patient of his own living six years after Dr Parsons asked about the presence of spleniculi, and their removal at operation and also inquired about the presence of gall stones. He agreed that in rickets there was mechanical depression only, but prolonged pre-existence in this disease would also lead to splenic enlargement.

Dr E. A. Cockayne agreed that in acholuric jaundice removal of the spleen removed the symptoms but not the disease. He inquired about x-ray treatment of cases where operation was refused. He had tried this ineffectively in one case, and he wondered if such treatment made a later operation more difficult. He thought he had seen one case of biliary cirrhosis in a child in which the spleen was just palpable. In splenic anaemia, since primary disease of the spleen appeared to go on to produce cirrhosis of the liver, early splenectomy was correct treatment, but diagnosis was difficult.

The PRESIDENT mentioned some difficulties in diagnosis, quoting a case in which a tuberculous pyonephrosis had been mistaken for a spleen. He said that in acholuric jaundice excessive fragility of the red cells was sometimes absent, and he described a case in a lad aged 18. Mayo had found concretions in the gall-bladder in three out of five cases of acholuric jaundice, and it was therefore possible to get acholuric jaundice with an added obstructive jaundice in such cases. He said he was rather frightened of splenic puncture in some cases, and he inquired if there were any risk.

Dr R. HUTCHESON, in reply, summarized the discussion which had arisen around the points he had raised. He thought that a clear history of splenic enlargement for some years before cirrhosis of the liver developed put a case out of the category of idiopathic cirrhosis, but it was difficult to lay down any hard and fast rule as to the period. He had not much experience of splenic puncture, but thought it ought to be performed more frequently. He believed that cases of "residual spleen" were not uncommon in which splenomegaly persisted.

Mr BARRINGTON-WARD agreed that spleniculi should be looked for and removed in operating upon cases of acholuric jaundice. Exploration of the upper abdomen should always be carried out in splenectomy cases. He thought that the effect of x-rays in producing adhesions had been exaggerated. Splenic puncture, in his opinion, was free from serious risks.

SECTION OF OPHTHALMOLOGY

Wednesday, July 27th

VISUAL EFFICIENCY AND WORKING ABILITY

Mr F. P. S. CRESSWELL, President of the Section, was in the chair at its first session. Dr FREELAND FERGUS (Rothsay), in opening a discussion on visual efficiency and working ability, pleaded that much work could be done by persons who suffered from very defective eyesight. He considered that too much stress had been laid on macular vision. Uncorrected myopes had little macular vision beyond their punctum remotum, but he knew of colliers with high myopia who had no difficulty in making as much money as the best sighted collier could, what was true of coal mining was true of almost every other form of manual work. In the field of vision important features were the sense of projection and the subconscious estimate of distance, which depended on such factors as the light sense, the colour sense, convergence, and parallax. Interpretation was not a physical process but a mental one. Many men who had sufficient sight for their work were thrown out of employment because of the discovery of a trivial defect in their sight which had caused insurance companies to refuse the risk. To a considerable extent the dole in this way was the necessary corollary of the Workmen's Compensation Act. The opener cited cases of men who had performed useful work with very defective sight, and of others whose employment had been lost on account of errors of refraction.

Sir JOHN PARSONS said that Dr Fergus had dealt with

a small example of a wide general principle, which was elaborated in his book *The Theory of Perception*. When a stimulus, whether tactile, visual, auditory, or of any modality, was applied to a normal animal it impinged on an already present complex perceptual pattern, which it consciously or unconsciously modified. Any such pattern was an integration of all the responses to all the stimuli which the animal was experiencing. It was not a mere mathematical summation, but a psychological integration *suu generis*. It was natural that biological, and especially visual, problems should have been attacked by mathematical treatment, but it was wrong to treat 6/6, 6/12, etc., as respectable members of the family of fractions. Standards of vision for different occupations were called for during the war, and the Ophthalmic Section of the British Medical Association passed a resolution at the Portsmouth Meeting which resulted in the formation of the Physiology of Vision Committee of the Medical Research Council. That committee had already a large amount of valuable work to its credit.

Mr BISHOP HARMAN said modern conditions of industry demanded good vision, and that meant standards of vision, for the purblind worker was likely to be both an inefficient worker and a danger to himself and others. Vision had many factors: acuity, field, colour and light sense, binocular vision, accommodation, and power of convergence. Each of these factors was a necessary part of the sense of sight that made a whole man. Each factor could be tested, and their tests must be simple, for they might have to be applied by the works doctor, and they must be understandable by both employer and employee, and recognized by both parties as reasonable, otherwise the doctor would be the promoter of strife rather than work. There had been attempts to depreciate the utility of some factors of vision. Acuity had been said to be less valuable than field, and so forth, he thought this was to be deprecated. Acuity marked the "vision" of those animals which were hunters, and "field" the hunted animals. Field made for general safety, but acuity was essential to skill and cunning. Man was easily first in this dual possession, and he "was a mighty hunter before the Lord!" The improvement in mentality, or the expression of it, that could be brought about in children by the correction of defective visual acuity was remarkable. So certainly established was this observation that it was now routine practice in the educational treatment of defective school children to determine the state of the vision when the mental state had been called into question. His experience led him to the conclusion that poor visual acuity was a common cause or associate of mental dullness and failure in attainment. The man who saw "men as trees walking" was out of joint with his time and place—a misfit that suffered accordingly.

Air Vice-Marshal DAVID MUNRO dealt with the visual requirements for flying officers and mechanics. At the end of the war 178 survivors applied for permanent commissions in the R.A.F., and of these 177 were found to have high visual acuity and perfect binocular vision. In other words, the men with lower standards of visual efficiency had dropped out. Mr CAIGER (Sheffield) spoke of the ease with which one-eyed men could accustom themselves to their loss.

The discussion was continued by Messrs Mackay (Hull), Spencer (Baghdad), Robson (Penarth), Coulter (Newport), the President, and Mr Tudor Thomas (Cardiff), and Dr Freeland Fergus replied.

EXAMINATION OF THE EYES IN YOUNG CHILDREN

Mr T. H. WHITTINGTON read a paper on "The examination of the eyes and eyesight of young children," in which he dealt with the necessity for and various difficulties met with during examination of children at different ages. He discussed the amount of error and visual defect which should be counted abnormal, and emphasized the necessity for a wide outlook upon the general mental condition of the child. The paper was discussed by Mr Bishop Harman, Dr Freeland Fergus and Sir J. H. Parsons.

Mr FRANK JULER read a paper on bilateral obstruction of the central retinal arteries which was discussed by Mr Caiger, Sir J. H. Parsons, and Mr. Frank Thomas. Mr COULTER (Newport) read a paper on the light sense in 100 cases of miners' nystagmus.

SECTION OF TUBERCULOSIS

Wednesday, July 25th

RELATION BETWEEN TRAUMA AND TUBERCULOSIS

Dr H MORRISTON DAVIES (Ruthin), President of the Section, took the chair at its opening meeting. The subject to be discussed was the relation between trauma and tuberculosis, especially from the point of view of compensation and accident insurance. In opening the discussion from the physician's standpoint, Dr NORMAN TATTERSALL confined his remarks to pulmonary tuberculosis, and excluded local skin lesions such as hutchers warts and the acute miliary form of the disease. The question to be answered seemed to him to be whether the accident localized a tuberculous lesion at the site of injury, or whether it merely mobilized an old focus. He thought that there was little evidence to suggest that injury produced a lowered resistance of the tissues to the tubercle bacillus, and that it was probable that an injury directly or indirectly affected an existing focus of the disease, such as a caseous root gland or a latent apical focus. With this opinion all subsequent speakers agreed. Dr Tattersall regarded the intensity of the injury as less significant than its nature and diffuseness, so that a crush from falling coal was more likely than a high velocity bullet to light up a latent lesion in the lung. A careful history of the case should always be taken, and the diagnosis verified by x-ray evidence. In most cases it could not be proved that, apart from the injury, the patient would later on have suffered from tuberculosis, but if the evidence convinced the observer that trauma had adversely affected the existing condition, it must be considered the materially effective cause of the ill health. In every case the questions to be asked were (1) Was the patient actively or passively tuberculous before the accident, and, if the former, what was his expectation of life? (2) Was the fact of injury definitely established, and was it of such a nature as to be likely to damage an active or quiescent lung focus? (3) What period of time elapsed between the injury and the diagnosis, and was this period covered by "bridge" symptoms? (4) Was the condition of the patient and the course of the disease such as might be expected if the injury had reawakened or aggravated an existing latent or active focus of disease?

Mr ROBERT MILNE illustrated his remarks on the surgical aspect of the discussion by means of lantern slides. He called attention to the difficulty which arose in compensation cases, when a patient with old tuberculous disease of the knee suffered from physiological weakness of the quadriceps muscle. The weakness of the muscle might cause the accident for which the patient claimed. Mr Milne was of opinion that the old figures of 15 or 20 per cent of tuberculous joints being caused by injury could not be upheld. Probably 5 per cent was the maximum proportion in which trauma played any part whatever. He had found that an examination of cases in which trauma was said to have caused tuberculosis showed that many conditions were included as tubercle which were not due to the tubercle bacillus at all. In such conditions as Kummell's disease, pied forcé, and coxa plana, trauma did undoubtedly play a great part. In other cases the history given was not unbiassed. Thus many patients stated that "My doctor says I must have hurt the joint", and the suggestion was sufficient to cause the patient to link up the tuberculous lesion with a supposed or at any rate an inadequate injury.

From the insurance point of view, Dr OTTO MAY described some of the difficulties with which the doctor was faced in compensation cases. His own attitude was to refrain from dogmatizing, but if there was a history of the injured part having never quite recovered from the injury, he was willing to testify as strongly as possible in favour of the workman. If, on the other hand, there was a clear interval of apparently full recovery between the injury and the onset of the disease, he refused to uphold a causal connexion between the two conditions, even if there was a possibility of its being true. This touch of dogma was more helpful in the dispensation of justice than the cleverest exposition of scientific agnosticism. If the medical practitioner came to the conclusion that the causal

relation, while possible, was not definitely probable, he should say so, and refuse to support the claim.

Sir ROBERT PHIPPS thought that while an accident did not cause tuberculosis, it might lead to serious developments. There was no object in dividing these cases into groups, since the tuberculosis existed before the trauma, and the whole question was a matter of degree. He emphasized two practical points: first, that not only one x-ray examination, but a series, was required, and secondly, that an accident might sometimes be a blessing in disguise by revealing the existence of tuberculosis which was previously unsuspected.

Dr BROWNLEE disagreed with the opinion that only a small percentage of tuberculous joints could be attributed to trauma. In a statistical inquiry he had found a history of previous injury in from 22 to 32 per cent of the cases, and in children a history of injury was frequently given, but he had to admit that amongst athletes, with whom he had frequently to deal, he had met with no case of tuberculosis following injury. He thought that the length of time up to which tuberculous disease might be attributed to an injury ranged from six months for a knee to two years for a spine. Dr CECIL WALL called attention to the effect of multiple minor traumata in activating quiescent tuberculosis. He regarded it as probable that such multiple traumata might act in the same way as fatigue by lowering the resistance even in those not previously infected. Dr JAMES CROCKET had found strain a prominent factor in producing exacerbation of the disease. Even massage might cause a flare-up and dissemination of the condition. Every tuberculous individual had his limit of strain. Dr W E WATSON said that an immediate report of the accident, and a continuous record of the symptoms which followed it, were essential if the patient's claim was to be supported. Dr H V CANTOR described the distress resulting to certain patients who had developed tuberculosis after the war, and had failed to make a claim to the Ministry of Pensions before 1925.

In reply, Dr TATTERSALL was gratified to find from the unanimous opinion of the Section that a blow had been struck against the notion of the implantation of the tubercle bacillus on damaged healthy tissues. He recognized fatigue and continued strain as causes of tuberculosis. In reply to Dr Cantor, he said that the Ministry of Pensions limit of seven years erred on the side of generosity, and had opened the door to much deception.

Papers were read subsequently on factors in the biochemistry of tuberculosis by Dr L S T BURRELL on the therapeutic value of the heavy metals, by Dr J C HOYLE on the serum calcium in experimental tuberculosis, and by Dr W H TYTLER on the tuberculin-active fraction of the tubercle bacillus. Drs J R GILLESPIE, H V CANTOR, and MARY NANNETTI contributed their experience in the use of sanocrysin. In the afternoon demonstrations were given of the after-results of surgical treatment of tuberculosis, and cases were shown in the x-ray department of the Cardiff Royal Infirmary.

SECTION OF RADIOLOGY AND PHYSIO THERAPEUTICS

Wednesday, July 25th

ULTRA-VIOLET RAYS AND THE GENERAL PUBLIC

THIS Section was presided over by Dr OWEN LEWELLIN RHYS (Cardiff), who, in opening the proceedings, said that the subject arranged for discussion was one of exceptional interest and importance to the public. He had no doubt that the audience would have been much larger but for the concurrent meeting of the International Congress of Radiology at Stockholm. The subject of ultra-violet rays was coming increasingly into prominence. Only recently, in Cardiff, an unqualified practitioner was sued for damage, done to a person's eye, and was called upon to pay. Two papers were read to the Section. The first was by Dr W E DIXON (Cambridge), who discussed the nature of the radiations, the physiological action of light generally, and the question of skin sensitiveness and of injurious effects, and insisted upon the need for careful examination of the patient before treatment. Treatment by radiation, he said, might be either beneficial or harmful, its employ-

ment by unskilled people might cause serious effects on the patient, and he suggested that the time had come when some sort of protection must be extended to the public. The second paper was by Dr C B HEALD (London), and dealt in particular with the harm which might be caused by electrical treatments. Dr Heald urged the need for the setting up of a register of persons regarded by a competent authority as suitably qualified to administer medical electricity. The register, he thought, should be somewhat on the pattern of that of the Central Midwives Board or the Dental Board. If the unqualified, unregistered chemist, dentist, and midwife were forbidden by law, then the unqualified electrotherapist, who certainly handled therapeutic measures as dangerous as those of an alchemist's shop, and performed operations as delicate as those of any midwife or dentist, ought to be put in the same position. The PRESIDENT thought that the most striking point brought out in the two papers was that here was an agent with potentialities of danger still largely unknown. Dr A J H ILFS (Taunton) thought that a penal clause regarding unqualified practice should certainly be imposed, and that it should also be made illegal for a registered electrotherapist to employ people who themselves were not qualified. When the register was compiled it should be made quite clear that admission to it did not imply permission to employ others who were not qualified. It should be made clear also to medical practitioners throughout the country that if they sent their patients to an unqualified radiologist they themselves were responsible for any damage that might be done to them. In reply to a question from a layman present, as to whether the proposed registrants would be required to be medical men or thoroughly qualified physicists, the PRESIDENT said that the qualification in physiotherapeutics must be defined hereafter, he took it that a certificate would be necessary from some board of examiners. Dr HEALD considered that a registrant should be required to produce some evidence of qualification such as the B.Sc. in physics, and should undertake that he would not act except under medical guidance as to treatment. Dr DIXON agreed with the views expressed by Dr Heald. It was the function of the physician to diagnose and then to prescribe treatment, but in a number of cases the treatment required was of a very special kind which the physician himself might not have the time, or perhaps not the skill, to carry out. The physician did not make up his prescriptions, they were made up by skilled people called chemists. If a medical man decided on ultra-violet light treatment he should put down in the prescription the light source, the area to be irradiated, the time, and so forth, and the administration of the treatment should be carried out by people trained in a particular way, that they should not be unskilled people was perfectly obvious. Dr MARIA ARMSTRONG (Ballymena) asked how far responsibility rested with the prescribing physician for any mistakes or unavoidably bad effects that might arise from special idiosyncrasies of the patient. In a cottage hospital with which she was connected "artificial sunlight" lamps had been instituted, and the committee had thought that the treatment might be in the hands of the masseuse, who, by her own admission, knew nothing about light treatment, and was not even qualified in electricity. The doctors, however, refused to allow the treatment to be placed in the hands of this woman, or to be responsible for any mistakes which might be made by her. Dr P W HAMOND (Croydon) said that this matter had been discussed in the Representative Meeting, and the conclusion arrived at was that no absolute rule could be laid down, and that, if legal proceedings resulted, each case would have to be decided according to the circumstances. Dr GARFIELD EVANS (Cardiff) considered that there should be a definite course of training undertaken by the people who were going to administer light treatment, and that a register should be set up. Dr T MARLIN (London) said that he had refused to instal a mercury vapour lamp (although it was very convenient for treatment) because he felt that this was an agent of which so little was known. He did not blame others for using the lamp, for results were obtained therewith which were not got with the carbon arc, but he thought it safer to stick to the more natural form of light.

SECTION OF TROPICAL MEDICINE

Wednesday, July 25th

HUMAN HELMINTHIASIS

Dr P H MANSON-BAHR, President of the Section, took the chair, and called upon Lieut-Colonel CLAYTON LANE, I.M.S. (ret.), to open the first discussion, on recent advances in the diagnosis and treatment of human helminthiasis. This opening paper will be found at page 191 of this issue. In the course of the discussion which followed the PRESIDENT said that he had found in the long needed accuracy of diagnosis now afforded by "direct centrifugal flotation" a valuable clinical advance. His clinical experience had made him positive that no infection with ancylostomes, however slight, should be neglected, both on its own account, and also as an important, because harmful, complication in other diseases. In his own hands, under conditions obtaining in hospital in England, carbon tetrachloride had proved a safe and effective drug in scores of cases of hookworm infection. There was, however, great need of standardization of anthelmintics.

Dr EDWARD HINDLE had noted, as the result of periodical examination of faeces of unselected patients in Cairo, that many recovered naturally from their hookworm infestation without any treatment. Prevention of reinfection was, therefore, of chief importance. Dr C M WENTON thought that the main objection to herd treatment without diagnosis appeared to lie in the unforeseeable lethality of one of the drugs used. Discovery of a safer, yet effective anthelmintic would remove that objection. Dr B M WILSON described the anti-hookworm campaign in Jamaica. A sanitary unit, dealing with village sanitation in general, and latrines in particular, took charge of the selected area, after their work was well established the treatment unit began to operate. This plan was based on the fact that treatment was largely wasted unless reinfection could be prevented. Deaths after carbon tetrachloride had occurred in Jamaica, and there thymol was now the drug of choice, and an effective one, against hookworms. Dr H M HANSCHELL recounted his experience of the success of "direct centrifugal flotation" in revealing very small ancylostome infections, where other not more time- or labour saving technique had failed to do so. In certain of his cases of secondary syphilis proving unexpectedly resistant to treatment, discovery by this method, and expulsion by thymol, of the small number of hookworms present had been followed by rapid clinical and serological response to the same antisyphilitic treatment. Carbon tetrachloride was a proved potent liver poison. It should not, therefore, be given to a purged and fasting patient unless sufficient glucose were given at the same time. For the same reason, to protect the liver, glucose should be given with antimony drugs also.

Dr J B CHRISTOPHERSON held that antimony acted directly on the schistosoma, though possibly not as antimony tartrate, but perhaps in an organic combination. There was no evidence that action of the drug on body tissues produced an "antibody."

Dr MANSON-BAHR read a communication from Dr F G Cawston of Natal, reporting success in treating "creeping eruption" with intramuscular colloidal antimony, or intravenous tartar emetic, injections, and also with carbon tetrachloride by the mouth and intravenously in human schistosomiasis, and in distoma infestation of cattle.

TRANSMISSION OF KALA-AZAR

Dr C M WENTON, in opening the discussion on this subject, pointed out that development of kala-azar and oriental sore parasites into leptomonas forms was strong evidence for an insect host. Leptomonas were essentially parasites of insects or other invertebrates. The flea had such an infection, which spread from flea to flea as small rounded bodies resembling leishmania. They escaped in the flea's faeces, were ingested by flea larvae, and appeared as leptomonas in the hind-gut of the adult flea. All insect leptomonas had that simple life-history. A sand fly which ingested parasites of kala-azar or oriental sore acquired leptomonas infection, but in stomach, oesophagus, and even buccal cavity, not in hind-gut. If such sand-fly fed through membrane into a fluid, it injected the leptomonas, it must therefore inject these also into wounds it inflicted.

in skin That no one had actually transmitted kala-azar or oriental sore by its bite was not due to lack of infectivity, for if the flagellates were removed by dissection from sand fly and injected into man's skin (oriental sore) or into hamster's peritoneum (kala-azar) infection occurred Perhaps a "receptive" condition was necessary to ensure infection from small doses injected through the proboscis Leishmania parasites would develop in the head-bug, but that could not be the host, for distribution of bug and disease differed, and if few leishmania were ingested by the bug only few flagellates developed In the natural host there was progressive increase of flagellates which attached themselves to cells of intestine No attachment occurred in the bug Association of canine with human kala-azar in the Mediterranean region gave rise to the theory of flea transmission, but careful experiments had failed to incriminate that insect Kala-azar parasites in the intestinal villi of man indicated their possible escape in faeces, and they had been demonstrated in the urine Contamination infection was unlikely, for the parasites could not withstand drying and would not survive in water Ancylostomes were possible ingesters of the parasites, but these helminths from cases of kala-azar had not revealed a trace of infection In the sand-fly, from a small dose of leishmania there developed large numbers of flagellates, attached to cells of the stomach and persisting for the life of the fly, thus the parasite behaved as in a natural insect host Probably the site of infection, originally in the hind-gut, had changed, or perhaps the sand-fly was not the original insect host Man having become infected from the original insect host, which might or might not now function, the sand-fly might have become secondarily infected from man A similar problem was presented by tsetse fly transmitted trypanosomes, where development in the tsetse fly was also an anterior one It was a posterior one in the primitive *Trypanosoma lewisi* in the flea, thus spread from flea to rat by the latter's ingesting flea faeces containing infective trypanosomes If the sand-fly were the vector, there were several possible modes of infection of man Flagellates might be occasionally ejected from the fly's rectum on to the skin, but the dose deposited would be even smaller than that injected from the proboscis Crushing of the sand fly gave a larger dose, which might be inoculable by scratching or by conveyance on the fingers to mouth or conjunctiva In India distribution of kala-azar corresponded with that of the sand fly *Phlebotomus argentipes* In China the disease was found only north of the Yangtze There was no information regarding existence of sand-flies south of it In India *P. argentipes* was most suspected, though development occurred also in *P. papatasi* In Northern China *P. major* var *chinensis* and *P. sergenti* var became infected, but the former was the better host With oriental sore *P. papatasi* in Palestine and Biskra had been infected, and in Baghdad *P. sergenti* In India a single infected *P. argentipes* had been captured in a kala-azar house With South American dermal leishmaniasis a single experiment suggested that *P. intermedius* might be the vector There were infections of animals—for example, gecko and chameleon—and plants with leptomonas, but nothing was known as to the relations these might have to the human diseases At present, therefore, the transmission problem of kala-azar and oriental sore centred around sand flies The extraordinary flagellate development of leishmania parasites in them was convincing evidence that they were the vectors

Dr I DWARD HINDLE then gave an account of recent work supporting the view that sand-flies were mainly responsible for the transmission of leishmania He pointed out (1) The specific nature of the development in the sand-fly, the stomach of which did not serve merely as a favourable culture tube, for, if this were the case, different strains of leishmania should develop equally well in any one phlebotomus species Yet, though four different strains of leishmania all developed into the flagellate stage in the Chinese sandfly *P. major* var *chinensis*, only the local strain of leishmania showed attachment of flagellates to stomach wall, and subsequent invasion of pharynx and buccal cavity This presence of flagellates in the anterior gut occurred only in the species of sand fly and with the

particular strain of leishmania that seemed to be transmitted by it (2) The virulence of the flagellates in the sand-fly, proved by inoculation of contents of infected flies into susceptible hosts As a corollary, since these flagellates were present in the infected fly's proboscis, and must therefore be inoculated into the skin when that fly fed, that fly's bites would sooner or later produce infection (3) The geographical evidence, in both India and China there was close agreement between distribution of kala-azar and that of the sand fly presumably responsible for transmission of the disease He criticized the transmission experiments hitherto carried out, and showed that with kala-azar they were inadequate in number to prove or disprove infectivity of the sand-fly In China kala-azar occurred in infants who, by reason of age, could not have been exposed to sand fly bites Low and Cooke's case of kala-azar in an infant born in England, whose mother had contracted kala-azar in India, demonstrated that the disease might be congenitally acquired The Chinese infant cases were doubtless of that kind Referring to the possibility of a second insect host in the cases of leishmania and trypanosoma, in which the flagellate stage occurred only in the anterior gut of the insect vector, Dr Hindle said that here the parasite had more or less lost the hind-gut flagellate stage in becoming more closely adapted for life in the vertebrate host Suppression of development in the insect host reached its limit in the disease "doanina," where the trypanosome had become a parasite of the vertebrate host only, and transmission was only by direct contact in coitus

Dr J B CHRISTOPHERSON pointed out the profound biological difference between the morphologically indistinguishable parasites of trivial oriental sore and fatal kala-azar Parasites of oriental sore experimentally inoculated into human beings always produced only oriental sore Clinical evidence suggested that oriental sore was the result of skin infection with insect flagellates, and kala-azar resulted after the flagellate had been further pathogenically modified by additional developmental cycle in another host His own experience of naso-oral and dermal leishmaniasis in the Sudan showed that lesions could be the result of inoculation by insect, and also by direct contact infection

Colonel A G MCKENDRICK, I M S, quoted results of his statistical inquiry in support of the theory of sand fly transmission of kala-azar Sir FRANK CONNOR described his cases in Baghdad and in India of familial and of multiple oriental sore His clinical observations of these and other cases, their personal habits and circumstances, favoured the view of the frequent occurrence of direct contact transmission of oriental sore The President, Dr P H MANSON-BARN, said he had observed oriental sore appearing in one parent in India, and six months after the family of four had returned to England, the sore appearing in the other parent and the two children before the lesion in the first parent had healed This suggested direct contact infection He pointed out that to Dr Wenyon we owed valuable and indispensable pioneer work on the transmission of oriental sore

SECTION OF THERAPEUTICS AND PHARMACOLOGY

Wednesday, July 25th

RECENT ADVANCES IN THE TREATMENT OF GASTRIC DISEASES

Dr W LINGDON BROWN presided over the meeting of the Section of Therapeutics and Pharmacology, the first subject to be discussed being recent advances in the treatment of gastric disorders Dr A F HUNTER, the opening speaker, described in detail the modern treatment of gastric and duodenal ulcer He said that the acid factor ought to be considered first, hyperacidity must be combated by diet and by such drugs as belladonna and alkalis The second factor—focal sepsis—was equally important, and search must be made in the nasal sinuses, and even in edentulous jaws, for possible overlooked sepsis Tobacco, worry, and fatigue were important causes, the last two made treatment in bed necessary in many cases Having shown charts illustrating the effects of drugs and diet on gastric acidity, he passed to after-treatment, and said that he was convinced that there was an ulcer diathesis, and

that a return to faulty dietetic habits must be prevented. Recent observations on the value of various antacid substances had shown that sodium citrate was efficient, and Dr HURST advocated the use of this and of tribasic magnesium phosphate rather than of sodium bicarbonate and magnesium oxide, because the latter substances would in some cases produce alkalosis.

Dr IRON BARNETT, who followed, dealt with treatment by diet and drugs. He said that the statement made a week before that the present treatment of gastric ulcer was merely the revival of a very old method was a complete misconception, the modern treatment involved the logical application of certain scientific principles over a period of time which must in some cases be somewhat lengthy. The essential principles were (1) the removal of septic foci, (2) the prolonged neutralization of hydrochloric acid, (3) the reduction of peristaltic movements by using frequent fluid feeds, (4) the maintenance of treatment long enough to secure permanent healing, and (5) the prevention of relapses by prophylactic treatment. In Dr Bennett's opinion every patient should be re-examined every three or six months for a long time after all symptoms had been relieved and complete recovery had occurred. In his experience the results of treatment by medical methods were eminently satisfactory.

Dr J. H. ANDERSON (Rathfriland Castle), in an account of the medical management of gastric ulcer, outlined the dietary used by himself and Dr L. I. Spriggs. They advised four weeks' institutional treatment, followed by four weeks' convalescence, and a third month during which the patient might gradually return to work. The appendix was a frequent septic focus, but if operative intervention

was required the patient should return to medical treatment afterwards. He supported the use of magnesium salts, although other antacid remedies were being investigated.

Dr PHILIP HAMILL stressed the importance of securing the active collaboration of the patient. He agreed with the opinion that sodium citrate was very valuable, especially on account of its effects in preventing the clotting of milk. Blood transfusion was a most useful adjuvant in cases with haemorrhage, and he had found the duodenal tube valuable in cases in which vomiting had been prominent. Dr A. P. CAWARIAS emphasized the fact that focal sepsis was only one factor, he regarded inborn errors of the endocrine and autonomic systems as of importance. He had found protein shock therapy of considerable value in producing alleviation of pain and disappearance of the signs and symptoms. Dr BUCHAN (London) was depressed by the unpalatability and complexity of the diet advised by Dr Anderson, and Dr J. F. BLUNTON (Nottingham) referred to the frequency of relapses during hot weather.

The PRESIDENT remarked on the increasing frequency of ulcer cases, but agreed that medical treatment was to-day very satisfactory. He strongly opposed the doctrine that ulcers should be excised on account of the danger of their becoming malignant, and held that the public had been needlessly alarmed on the subject. In his reply Dr HURST reviewed the results of surgical treatment, and expressed the opinion that medical treatment was infinitely safer, and satisfactory in the vast majority of cases.

Dr J. MANSON of Warrington then read a short paper on the effects of valerian in gastric disorders, this was discussed by the President, Dr Hamill, and Dr Foster of Worcester.

Rebichus.

SPECTACLES

A THIRD edition of Mr A. S. PERCIVAL's book on *The Prescribing of Spectacles* has been issued. It is to all intents and purposes a new book, for so much new work has been done in optics since the last edition that the author has practically rewritten his material. Under this most modest title Mr Percival offers a masterly work in which all the craft and art and science of the skilled ophthalmologist and mathematician and worker in lenses are displayed to the reader. The author is a master in mathematics, he revels in formulae. But let it not be supposed for one moment that his work is so altogether mathematical that it is of little use to the average hand and the average head for figures. Mathematics apart, the book is full of practical observation and advice, attention to which will greatly advance the skill of the already skilful. Some effects which we commonly obtain by traditional rule of thumb are here explained and placed upon a properly authenticated basis of proof. Many of the pitfalls in prescribing are indicated, and well marked for the warning of the unwary. Particularly good are his observations upon the intricacies of the use of periscopic lenses, of bifocal lenses, and of prisms. No less useful is his comment upon the use of the ophthalmometer, and we are inclined to think that many, if they had read and checked his observations thereon, would have spared themselves the expense of highly complicated instruments, and concentrated upon the perfection of their skill in retinoscopy. Mr Percival's work is a credit and an ornament to British ophthalmology, and that is saying a good deal, for there has never been wanting a succession of British ophthalmologists who were able surgeons and brilliant mathematicians.

SPECIAL CYTOLOGY

THE remarkable advances made in experimental cytology in recent times have placed new methods in the hands of investigators engaged in the study of the physiology and pathology of the cell. A general survey of this field from

the new points of view was given in Cowdry's *General Cytology*, published four years ago. This volume, which was the collective effort of a number of workers, gave a general account of such topics as cell permeability, tissue culture, microdissection, cell inclusions, and the chromosome basis of heredity. The work just published is entitled *Special Cytology*.² It is the joint production of thirty-five authors, under the editorship of Dr E. V. COWDRY, and is published in two volumes of approximately seven hundred pages each, with nearly seven hundred figures in all.

In the preface the editor explains that the principle underlying the organization of the work has been that each section should be "entrusted to an investigator who, through his own researches, has personal knowledge of the subject on which he writes." The result is that the work is divided into thirty-seven sections. Such a method has undoubted advantages. It also has its disadvantages, in that a certain amount of overlapping is almost inevitable. We find, for example, the Kupffer cells of the liver described in the section on the cytology of the liver, and again in that on the macrophages. A certain noveness is also bound to occur in a collective work. The editor says that in order better to understand physiological processes, or more intelligently to treat disease (which amounts to much the same thing), the contributors have resorted to a study of the fundamental living units—that is to say, of the cells of the tissue with which they are concerned. The purpose of the book is therefore to present a detailed account of the "types of cells which make up the body, and which serve different functions." Certain of the sections are an admirable practical expression of this aim. We might cite as illustration the sections by Maximow on lymphocytes and plasma cells, and on macrophages, which are of particular interest to pathologists. The result of the application of the new method of research to these cells is described—what has been learnt from tissue culture, intra-vitam and supra-vital staining, and the result of applying the best modern methods for the study of cytoplasmic structures. Some readers will regard the beautiful illustrations as the most valuable part of this contribution.

We have particularly noted Maximow's contribution to this work as dealing with topics of special interest in pathology at the present day. Other sections might equally well have been chosen for special commendation as

¹ *The Prescribing of Spectacles*. By Archibald Stanley Percival M.A. M.B., B.C. Cantab. Third edition rewritten. Bristol: John Wright and Sons Ltd. London: Simpkin Marshall Ltd. 1928. (Cr 8vo p. 239 29 figures. 15s. net.)

² *Special Cytology*. Edited by Edmund V. Cowdry. In two volumes. New York: P. B. Hoeber, Inc. 1928. (6 1/2 x 9 1/2 pp. 1548, 633 illustrations.)

fulfilling the aim set out by the editor in his preface, but, judged from this point of view, some of the contributions are disappointing. We have some chapters without a single illustration at high-power magnification of the fundamental cell types. Others are badly illustrated from this standpoint. To us it seems that more attention might have been paid in the illustrations to representing the changes that occur in cellular structure under varying conditions of functional activity. Diagrams representing alterations in cell structure under varying conditions of metabolism are of much greater value to the average student than mere description. They also have the advantage of conveying to the trained inquirer at a glance more than a great deal of descriptive writing is able to do.

Finally, there is the introduction by Dr Alexis Carrel. We deal with it last because it points rather to the future than to our present knowledge. It emphasizes the possibilities of the new methods of tissue culture and microdissection. It points to our ignorance of the chemistry of protoplasm, and expresses the hope that "some chemist will take up the study of vital staining in collaboration with a cytologist, as there is a need of new dyes for the discrimination of cytoplasmic structures."

Regarded as a whole, this work is a valuable contribution to biological and medical literature. It represents the most concise and up-to-date work on the cytology of the mammalian tissues. It will undoubtedly be of great value to students of cytology and microscopic anatomy, and to all scientific workers who require a knowledge of the structure and function of cells.

GENITO-URINARY SURGERY

THE second edition of Dr G. MARION'S *Traité d'Urologie* contains several new chapters and a large number of additional coloured plates. Since the appearance of the first edition in 1921 advances in genito-urinary surgery have been made in various directions, particularly in methods of diagnosis. For this reason much has been added on the subject of cystography and pyelography.

Dr Marion has had an immense experience which few men can rival. He may be regarded as the senior exponent of genito-urinary surgery in Paris. His style is dogmatic, and he defers little to the opinion of other surgeons. In a less senior man, and in one who had not received worldwide recognition as a leader, this might be regarded as a fault, but actually it will be found to increase rather than diminish the value of the book. Too many medical works are found on examination to be but a compilation of the opinions and writings of others. Unlike these, Marion's *Traité d'Urologie* is the outcome of a life devoted to the subject of urology. Few people, for example, could have written as he does on the treatment of prostatic obstruction, and have furnished the numerous small details which can come only from long practical experience. It is because the information to be found within its covers is essentially practical that this book is so valuable. Even where we disagree with the author's opinions we feel bound to pay deference to them, since they are the outcome of a very wide experience. That he refuses to admit the existence of stenosis of the bladder, of the fibrous prostate, or of the fibrous bars of the American school of urology as clinical entities may cause us surprise, but we feel it is an honest view that has not been lightly arrived at. We can only assume that Marion's heterodoxy in this instance is to be explained by a difference of terminology, and that he would include such cases under his heading of congenital hypertrophy of the bladder neck. At the same time, we cannot help feeling that more often than not this type of obstruction is acquired rather than congenital in its origin.

The excellence of the coloured plates was noted in our review of the first edition, all that it is necessary to say is that these have been almost doubled in number and that the previous high standard has been maintained. Marion's *Traité d'Urologie* has established itself as a standard work of reference, and the new edition will enhance its reputation.

* *Traité d'Urologie*. Par G. Marion. Deuxième édition entièrement refondue. Paris: Masson et Cie. 1928. (64 x 81) Tome I pp 663 196 figures 28 plates. Tome II pp 529 280 figures, 3 plates. 200 fr sans majoration the two volumes.)

SENSATION

A book with a title so attractive as *The Basis of Sensation** will not fail to attract a public of diverse interests. Lest these be deceived, let it be known that Dr E. D. ADRIAN'S book is a study in experimental physiology. It employs neither the language of metaphysics nor yet that of psychology. Its vocabulary is that of the physiological laboratory. The book is, in fact, a review by the author of his own brilliant researches during the last few years into the nature of the nervous impulse and its relations with external stimuli and with the central nervous system. The philosophical reader should not be deterred by this description. The work of Dr Adrian is recognized to be a fundamental contribution to the problem of the relation of the organism to its environment. Moreover, his language is very simple.

The argument centres around the three words—rhythm, adaptation, and integration. It appears that a stimulus to an organ must achieve a critical intensity in order to evoke any sensory recognition. Above this level it releases a rhythmic discharge of impulses whose rhythm varies with the intensity of the stimulus. If these impulses are crowded together the sensation resulting is intense, if they are separated by long intervals the sensation is correspondingly feeble. Moreover, the amount of information which the central nervous system can glean from a single organ is governed by the rate of adaptation of that organ to a constant stimulus. There is little to distinguish the messages sent out by different receptors in response to such stimuli as heat, light, touch, etc., but the rates of adaptation of these various organs are characteristic. In this way the quality of the sensation evoked must depend apart from degrees of intensity, upon the path which each particular impulse must travel. Finally, there occurs somewhere, somehow, a process of integration of these messages which traces the rise and decline of a sensation as a fair copy of the rise and decline in the excitatory process in the receptor. Dr Adrian recognizes that here is the great gulf fixed. We can only say with him "Perhaps some drastic revision of our systems of knowledge will explain how a pattern of nervous impulses can cause a thought or show that the two events are really the same thing looked at from different points of view. If such a revision is made I can only hope that I may be able to understand it."

NUTRITION AND DIET

THE number of textbooks and monographs dealing with dietetics is now so large that the reader is justified in adopting a severely critical attitude with regard both to subject matter and mode of presentation. Many of these works he will very justly condemn as being ill-balanced, ill-informed, or tedious. *Nutrition and Diet in Health and Disease*,* by Professor McLESTER, must, however, claim both his admiration and his gratitude. At first sight its bulk is a little disconcerting, but the size is largely explained by the insertion of tables which, while undoubtedly invaluable in certain circumstances, yet are so arranged that they do not intrude themselves unduly on the general reader who, for the moment at least, is not interested in them. The book is characterized by a sane and well-balanced outlook and a comprehensive and succinct treatment of the several aspects of dietetics. The opening chapters give a clear and readable exposition of the physiological principles of nutrition. Following this, there is a brief discussion of the phenomena of digestion. In the section dealing with "nutrition in health" the author deals with the physiology of the various classes of food-stuffs, their availability and cost, and with the normal diet for persons of different ages and varying financial resources. There is also a chapter on infant feeding. The practical details contained in this section are, we feel, of particular value, though, since they are written for the American, the English reader has to translate them for

* *The Basis of Sensation*. By E. D. Adrian. M.D. F.R.C.P. F.R.S. London: Christophers. 1928. (Demy 8vo, pp 122 31 figures, 7s. 6d. net.)
* *Nutrition and Diet in Health and Disease*. By James S. McMaster. M.D. Philadelphia and London: W. B. Saunders Company. 1927. (6 x 9½ pp 783 365 net.)

himself into terms of more familiar materials and dietary habits. The rest of the book is concerned with nutrition in disease. The ground covered is wide and the method of classification good. The question of slight but chronic vitamin deficiencies is considered, and many helpful practical details have found a place. The work of Ijstein on nephritis is dismissed perhaps a little too briefly, the discussion of differential diagnosis and treatment of obesity and leanness are, on the other hand, excellent. We note Professor McClester has made a slip on p. 70, where the author suggests that tryptophan is concerned in the formation of thiroxine, and is 'pot-licker,' on page 88, a misprint or an Americanism?

TRAPS FOR TRANSLATORS

Les faux amis,⁶ notwithstanding its title, is, as its authors point out, not a piquant love story. MM. MAXIME KESSLER and JULES DEROCQUIGNY have compiled a list of English words which, while similar in appearance to certain French words, have in fact a very different meaning. They doubt, for example, if the motorist would be grateful to the French translator of an English book who advised his readers to apply Ambroise Paré's huile de castor to his clutch instead of huile de ricin. The former would probably prove a false friend. And if, with Carlyle, the translator stated that of two universities, "Cambridge is decidedly the more catholio" (catholique), most of his readers would jump to a wrong conclusion. Such a book as this must be of the greatest use to those who undertake to interpret the thoughts of one nation to the understanding of another, and similar work might well be done for other languages. But we venture to think that the authors made a mistake in not associating with themselves in its preparation an Englishman with a knowledge of French. It is plain that they relied largely on the *New English Dictionary*, and in the list of acknowledgements for assistance no English name appears. As a result the book is not wholly free from the strange little mistakes which it seeks to help others to avoid. Again, the authors have relied too much on Shakespeare as an exponent of English usage, and consequently have laid stress on many archaisms. Who, for instance, would have connected *souiller* with the verb "to file"? Yet a quotation from *Macbeth* is produced which may possibly bear this meaning. On the other hand, there are evidences of acquaintance with some of the latest Americanisms, as in the use of the expression "to jacket documents." The close examination of the meanings of words has led MM. Kessler and Deroquigny into unnecessary, and doubtfully valid, refinements. Thus the English word "bier" must undoubtedly come from the French "bière." But the authors are concerned because *bière*—unless "wet"—is now usually applied to a coffin, while a bier is no more akin to a brancard or civière. Surely the Frenchman would not attribute to the last two words any meaning other than that of litter or stretcher, and bier would still be reproduced best by translating it *bière*. The book is remarkably well put together, it displays much erudition, and, as suggested by M. Louis Cazamian in his introduction, it should help to cement the entente cordiale by removing erroneous interpretations of word and phrase in the two languages.

NOTES ON BOOKS

In recently published writings by Mr. VINCENT NESFIELD a method of treating deafness by operation has been advocated. Those who fear to condemn this method because there may be something in it have perhaps afforded undeserved encouragement, which has resulted in the production of a book.⁷ The author states that the mastoid antrum always disappears in middle ear catarrh, he does not distinguish between the attic and the antrum, the aditus ad antrum from the attic is apparently unknown to him as such, for he calls it

the fenestra spes, he is unable to make a diagnosis of otosclerosis without an exploratory operation on the temporal bone, and in describing his operation he refers to the sigmoid sinus as the external jugular vein. Further comment seems needless, but if there still be any who regard this operation seriously chapter iv, entitled "Some cases, will disillusion them. The author gives notes of nine cases, but, incredible as it may appear, there is no record of hearing tests. One of the patients had suffered from acute inflammation of both ears for two years, another was able to hear a bell after the operation—an improvement scarcely worth the danger and discomfort of an operation—and another improved her hearing still further after the operation by attending classes in lip reading.

In his scholarly work on *Medical and Allied Topics in Latin Poetry*,⁸ Dr. HEINRICH OPPENHEIMER has collected from the poets of the Augustan and Silver Ages all the passages more or less remotely connected with medicine in the widest sphere of the term, with an English metrical version in the footnotes. Extracts will be found applicable to almost every branch of medicine, including infectious diseases, various internal disorders, balneology and hydrotherapy, toxicology, alcoholism, insanity, sexology, surgery, midwifery, dermatology, and diseases of the eye, ear, nose, and throat. Of the twenty-six poets laid under contribution, those most frequently quoted are the satirists and comic dramatists, such as Horace, Juvenal, Martial, Plautus, and Terence, the philosopher Lucretius, and Ovid, whose value as an historian of the social life of ancient Rome is universally recognized. The work, as the author and publishers surmise, is not likely to have a wide circle of readers, but it will be welcomed alike by the medical historian and antiquarian.

The fourth edition of the late Dr. LEO HIRSCHLAF's manual on hypnosis and suggestion treatment⁹ appears with a preface by Professor J. H. SCHULTZ, who justly calls attention to its high practical and clinical value, both as a textbook for students and also as a handbook for those who use these methods in general practice. In less than 300 pages a good account is given of the history of this subject, with special reference to the influence of Liébeault, a concise catalogue of the conditions in which this method is useful, a careful outline of the methods, and a critical appreciation of the degree of benefit likely to be obtained. Dr. Hirschlaff had little sympathy with the followers of Freud and similar exponents of the sub-conscious self, and this may, for some, limit appreciably the utility of this handbook, but it can be recommended to those who are interested in the physiological methods associated with the names of James Braid, Forel, Charcot, and Bernheim. Two useful indexes—one of authors, the other of subjects—facilitate reference.

We found it difficult at first to say for what class of readers Dr. OSCAR LEVIN intends his book on *The Care of the Face*.¹⁰ It is not sufficiently technical for the medical practitioner. Although written in a popular and breezy style, it lays down no rules for the guidance of the otherwise uninstructed patient. In the end we have come to the conclusion that its real object—an exceedingly worthy one—is to induce the numerous members of the public, of both sexes, who are interested in facial conservation to abandon the nostrums of the quack and the beauty parlour and to seek instead the consulting room (or in American the office) of the properly qualified and registered dermatologist. May his efforts be crowned with complete success!

One of the most recent additions to the To-day and To-morrow Series is *Metanthropos or the Body of the Future*,¹¹ by Professor RONALD CAMPBELL MACFIE. While admitting that it is impossible to argue from man's far past state as a 'glorious worm' to the far or even near future, or to infer that the rate of progress in the future will be the same or nearly the same as in the past, the author is on the whole optimistic. The most striking feature in man's evolution has been the growth in size and complexity of the neopallium, and Professor Macfie considers that the metanthropos of the future will live a fuller and richer life than the man of to-day, partly because sexual selection, based on intellectual rather than on physical attraction, will have improved his brain, and partly because previous generations of brains will have improved his brain's environment in the way of books, wireless, and so forth.

British Medical Journal.

SATURDAY, AUGUST 4TH, 1928.

THE CARDIFF MEETING

ALL who took part in the ninety sixth Annual Meeting of the British Medical Association, held at Cardiff last week under the presidency of Sir Ewen Maclean, will agree that the two salient features were the admirable organization and the hearty welcome everywhere accorded to the visitors.

The beauty of the chief buildings of Cardiff is enhanced by their position in Cathays Park, and excellent internal arrangements add much to the convenience of their close proximity one to another. The Lord Mayor and Corporation placed at the disposal of the local executive the magnificent City Hall for the annual session of the Representative Body, and the same assembly room, with its fine ceiling and Ionic decoration, made an appropriate setting for the presidential, civic, and Branch receptions, and for the Annual Dinner of the Association, reported in the *Supplement* this week. The governing body of the University College of South Wales and Monmouthshire, by granting the use of its impressive building for most of the Sectional meetings, for the ladies' club, and for various general purposes, deserves also a warm tribute of thanks, many members from other parts of the country will henceforth take a livelier interest in the progress of higher education in the Principality. Some of the Section meetings were held in the Technical College, by kind permission of the Education Committee of the Cardiff Corporation. The beautiful National Museum of Wales attracted many visitors throughout the week, excellent musical performances were given daily by the National Orchestra of Wales, and the collection of manuscripts and other objects illustrating the contrasts between ancient superstition and modern medicine in Wales was much appreciated. The Council of the Museum, moreover, entertained members of the Association there at a delightful reception on Friday evening. Cardiff Castle, with its beautiful grounds and ancient buildings, was greatly admired by the large number who accepted the generous hospitality of the Marquess and Marchioness of Bute at the garden party on Thursday, which also marked the opening of the festivities in connexion with the coming of age to day of their eldest son, the Earl of Dumfries. The Marquess, moreover, invited members of the Association on more than one occasion during the week to Caerphilly Castle and Castell Coch, and entertained a large party to dinner in the banquetting hall of Cardiff Castle. Some account of the many other agreeable social functions will be found in the *Supplement*.

As had been expected, the attendance at this Annual Meeting fell short of the very large figure recorded last year at Edinburgh, but during the week some 1,300 members registered, not counting the many wives and daughters, and all were deeply impressed

with the cordiality of their reception. A considerable part of the scientific programme of the meeting had been planned with an eye to practical questions of the hour, and the debates in the principal Sections drew large audiences despite the many pleasant diversions provided elsewhere. There were no doubt other reasons, but the unusual number of subjects of general and topical interest, and even of controversy, must have been responsible in some measure for these good attendances. Arrangements have been made to publish in the *British Medical Journal* during the next three weeks fuller summaries than heretofore of each day's proceedings in the Sections. By this means it is hoped to arouse greater general interest than has been possible in previous years, when detailed reports of the scientific and clinical discussions were spread over five or six months. The first instalment of our concise accounts of the work of the Sections will be found at page 198 of the present issue. As usual, the Pathological Museum (housed this year in the Library of the University) was a great centre of attraction, illustrating as it did several of the discussions and reinforcing points made by word of mouth.

Of the great mass of political and domestic business carried through by the Representative Body of the Association, under the courteous and vigilant chairmanship of Dr Hawthorne, we need only say here that, though in several important matters substantial progress has been made, in two others the outcome of much debating has been a reference back to Council, while in regard to the International Union of Medical Organizations and the direction of infant hygiene clinics for the middle classes the Council's recommendations have been reversed. Notwithstanding the efforts made by electricians to improve the acoustics of the hall, many speakers found it difficult to get contact with their audience as a whole, and this favoured neither the presentation of an argument nor the dispatch of business. We publish in this week's *Supplement* the remainder of our full report of these proceedings, and on another page will be found the conclusion of a series of notes giving impressions of the Representative Meeting by an onlooker in medical politics.

It is almost a truism that an assembly like the Annual Meeting of 1928 takes its tone and colour from the personality of those who act as hosts. Sir Ewen Maclean, with his genial grace of manner and his intimate knowledge of the Association from past work in the middle of its affairs, had singular advantages for the leading part his colleagues called upon him to play, and the success of the meeting owed much to his high conception of what a President should be and do. His chief of staff, Dr Gilbert Strachan, upon whose shoulders lay the heavy burden of local secretariatship, earned general praise for his unremitting work and inexhaustible good humour, and Dr Strachan would be the first to wish that a share of the credit for this effective administration should go to the deputy general secretary, Dr Tudor Thomas. The good offices of the Lord Mayor and Corporation have been referred to, and among many others who worked unselfishly to make the week a success must be mentioned, in particular Dr W. E. Thomas (vice chairman of the General Committee), whose friendly greeting made everyone feel at home in South Wales, and the city,

treasurer, Mr John Allcock, who gave skilled service as honorary treasurer of the Meeting. All these may feel assured that their labours are highly appreciated, and will be held in grateful remembrance by everyone who attended the Cardiff Meeting.

ETHYL PETROL.

We summarize elsewhere (p 219) the interim report, issued at the end of last week by the Departmental Committee, dealing with the risks to health of adding lead tetra ethyl to petrol for use in the internal combustion engine. The Committee states in brief that any poisonous effect on the users of this spirit or on the public at large has yet to be proved. The only preparation of this kind on sale in Great Britain is "ethyl petrol," which is petrol with lead tetra ethyl dissolved in it in the proportion of 1 part in 1,300 by volume. No European country has, as yet, used the spirit to any extent, and most of the evidence on which the Committee bases its report has been of American origin, in which country the spirit has been largely employed for some years past.

Several interesting facts emerge on reading the report. Lead tetra ethyl in the pure form is extremely toxic. It is lipid soluble, and when placed on the skin is absorbed quickly and may cause death. Unfortunate accidents happened in the United States a few years ago during its manufacture and before its very poisonous nature was appreciated. It is easy to demonstrate that a few drops placed on the skin of small laboratory animals are absorbed, and may induce death in a few days, but this by no means proves that lead tetra ethyl dissolved in petrol in the proportion stated is toxic. The evidence so far available goes to show that the lead compound is held by the petrol so firmly that its absorption by tissues does not occur. Carbolic acid in oil lacks antiseptic properties because the oil holds the carbolic acid and leaves none available for destroying bacteria, it seems possible that the same principle may hold for ethyl petrol. A second danger might arise from inhalation of the vapour, but the report informs us that no lead is evaporated in the first half of any ordinary distillation at body temperature. It is, however, less reassuring about what happens when a considerable amount is spilled about garages and allowed to evaporate slowly, perhaps to dryness. Here, undoubtedly, some lead would vaporize and find its way into the atmosphere, though in amount it would, perhaps, be negligible. The third possible danger of using this petrol is one which most nearly concerns the public, a small amount of lead must be deposited from the exhaust gases of all motor cars using ethyl petrol. This will no doubt continue to be insignificant for a long time to come, but if all cars used ethyl petrol it is difficult to believe that this lead may not be a potential factor of some importance to the public health.

Lead tetra-ethyl has an action different from that of ordinary lead salts, in that after absorption it is distributed in the body in an unusual way, the central nervous system absorbing relatively large amounts. Here it is apparently converted slowly into ionic lead, and induces cerebral effects which are not usual with inorganic lead. It may be compared with lipid-soluble arsenic compounds such as salvarsan, which are specifically absorbed into certain tissues, where ionic arsenic is slowly liberated.

It should be particularly noted that this carefully phrased report does not say that petrol containing lead tetra ethyl in the proportion of 1 part in 1,300

by volume is harmless, but rather that there is at present no proof that it is harmful. We await with much interest the Committee's final verdict, which, no doubt, will afford some positive proof on one side or the other.

ANNUAL MEETING NOTES.

The Representative Meeting

In the *Supplement* this week we conclude publication of the full report of the Annual Representative Meeting at Cardiff. The short notes printed below are intended to give, in very general and informal terms, an outline of the course of the discussions during the latter part of the meeting.

Monday, July 23rd

The outstanding items on the agenda for Monday were the report on puerperal morbidity and mortality, the memorandum on the Report of the Royal Commission on Lunacy and Mental Disorder, and the speeches of the Dominion and Colonial representatives on the report on overseas Branches. The puerperal morbidity and mortality report met with but little criticism, but its presentation gave the chairman of the Committee, Sir Ewen Maclean, an opportunity, of which he made good use, to emphasize the importance—international, national, individual, and professional—of its subject and its recommendations. After his clear and detailed exposition of the method pursued by the Committee, the nature and object of the proposed action on the part of the Association, and the development of public policy since the drafting of the report, the amendments proposed by Edinburgh and Leith and South-West Wales served to illustrate the keen interest of the Divisions and Branches in the work already done, and their desire to accept full responsibility for development along the proposed lines, rather than to strike any note of criticism. The discussion of the memorandum on lunacy and mental disorder was, on the whole, disappointing. The representatives were not, it is true, prepared to follow Dr Roxburgh and Dr Temple Grey in referring the report back on the ground that specific action had not been taken to promote legislation for the protection of the practitioner in the interval during which the policy now recommended for the purpose had been under review. Nor did they seem, on the whole, inclined to dispute the primary importance of securing means for adequate treatment. But something better might have been expected in the circumstances. The Divisions had had a full year to reflect on the issues at stake, the Committee on Lunacy and Mental Disorder had had a year in which to consider the exact terms best fitted to embody principles already fully debated, or to modify propositions which had failed to secure support at Edinburgh, and during a great part of that period there had been no specially hard case before the courts in connexion with certification in lunacy to alarm the profession. Yet the debate was characterized by a general confusion of terms and uncertainty as to facts, as opposed to feelings, and a tendency to discuss at large and at cross-purposes instead of to join issue on specific points. Of the amendments proposed some were already explicitly covered by the terms of the memorandum, others were so worded as to obscure rather than clarify the particular points under discussion, whilst the terms of the two principal amendments actually carried were such as to reduce them, in form if not in intention, to pious opinions. The overseas report was short, and contained no recommendations, but it gave the meeting the pleasure of hearing from Mr Leopoldt, Dr Spencer, and Sir Malcolm Watson something of the work of the Association in and for the overseas Branches. Mr Leopoldt's shrewd criticism of the outlook and procedure of the Representative Body

from the standpoint of a member from South Africa, Sir Malcolm Watson's testimony to the Association's work to secure efficiency for the medical service in Malaya, and Dr Gordon Spence's triumphant claim to a membership of 100 per cent in the nine-years-old Mesopotamian Branch could not but appeal powerfully to the imagination and sympathy of the meeting. On the items outstanding from the Medico-Political report two discussions merit special notice. That initiated by Dr Peter Macdonald on the motion from York in connexion with ambulance lectures, and developed under the reduced time limit, was an ingenious piece of propaganda, and the rejection of the motion left the representatives pledged, personally at least, to a far more active support of the existing policy of the Association than has been general heretofore. The debate on the classically phrased proposition from Edinburgh and Leith for reinforcement of the voluntary system for controlling venereal diseases by imposing a "compulsitor" on infected persons allowed the Representative Body to express, by the decisive rejection alike of the motion and the amendment suggested by Mr Turner, its opinion on a question which has been much before Parliament and the public in the past twelve months. The remainder of the day's session was given to the report on medical benevolence, and the points arising from the opening recommendation on public health.

Tuesday, July 24th

The business remaining for discussion on Tuesday included three of the most important matters on the agenda, and it was unfortunate that the necessity for bringing the session to an end by 4 o'clock not only imposed a time limit for speeches early in the proceedings, but also reduced to a hurried formality the presentation of the Scottish, Irish, and Naval and Military reports, and the votes of thanks to those who had contributed to the success of the meeting. On the Public Health report the motion defining the extension and limitation of the functions of an M.O.H. was passed as it stood, after a discussion which showed at once the thorough manner in which the Committee had gone into the whole question, the adequacy of the terms in which it had embodied its recommendation, and the need for further light on points whose elaboration was beyond the compass of the Annual Report of Council. The extension of the time limit for temporary adjustment of the salary scale for public health appointments in Scotland was another matter on which full explanation of the conditions in the course of debate was all that was wanted to satisfy legitimate doubts about the need for this expedient. The remaining items under public health, including the motion from Edinburgh and Leith on noise and public health, went through without controversy—though this last resolution was one in which acceptance of the principle may well prove easier than its translation into effective action. The debate on the section of the national health insurance report dealing with spa treatment for insured persons was of considerable interest. Dr Dain, with the support of Dr Brackenbury and Dr Thomson, was able to satisfy the representatives as to the details of the proposed scheme, but failed, even after Dr Brackenbury's *reductio ad absurdum* of the proposed amendment, to carry the basic definition of spa treatment, which was referred back for further consideration. This result may have been due to pressure of time and the consequent difficulty of finding a better formula. The Representative Body, as a whole, clearly felt that the claims of sea water should not be ignored, though reluctant to relax the safeguards applied by the Council's definition. The debate on co-ordination of hospital provision was perhaps of more interest than any that had gone before, and its outcome was a signal success for the policy drawn up by the Hospitals Committee. The real point to be decided was whether hospital co-ordination

on the basis of co-operation in the common interest is a practical policy, or whether the dominant consideration must be the individual interests of the several existing hospital systems and the bodies of workers concerned in promoting their efficiency. By its decision the Representative Body proclaimed that the medical profession is ready for the co-operation necessary for co-ordination, and left the Council in a position to take steps to secure that the voice of the profession is heard before any Governmental action by way of a partial readjustment can prejudice the main issue. In the discussion on criteria for practitioners treating private patients in paying wards or in nursing homes attached to hospitals a different note was struck. The danger of prejudicing the hospital policy of the Association by a new definition which might lead to dissection in areas where working arrangements are established, the difficulty of setting up criteria equally applicable in so many differing circumstances, and the fact that the Association's policy in regard to middle-class hospital provision has yet to be formulated—all these combined to send the recommendation back for further consideration. Among the motions brought up at the end of the meeting and accepted by the Chairman for consideration in the coming session, that by Dr G. W. Hurst of Wellington, New Zealand, requires special mention, because it voiced a demand which has been growing more and more insistent since the war. The need for better post-graduate facilities for overseas members becomes more urgent every year, and it is only natural that these members should look to the Association at home to take effective action on their behalf.

Popular Lecture: Medicine in Art.

The New Theatre, Cardiff, was crowded in every part for the Popular Lecture delivered by Sir Berkeley Moynihan Bt., P.R.C.S., on Friday evening. The lecture, which was illustrated by many lantern views, was on the subject of "Medicine in art," and although some doubtless had heard the substance of it before, the charm of its delivery, the many humorous and affecting touches, the culture and wisdom which lay behind it, would have made it worth hearing for the twentieth time.

Sir Berkeley Moynihan began by remarking on the heavy load of responsibility which the medical man had to carry. The doctor held in his hands the health and lives of his fellow creatures. When he ended his arduous day's work—a work which had made huge demands upon his nervous as well as upon his physical energies—he realized often that virtue had gone out of him. Even if he failed to realize it, it was none the less true. That store of virtue could be replenished in no other way so well as by the contemplation of things of beauty. It was of little use to play the indifferent round of golf or indulge in some other form of physical exercise, he had better devote himself to some quiet contemplation of art—beautiful furniture, china, pictures, books. Hero was indeed rest for the weary mind. The lecturer then went on to speak of how the alliance between art and medicine was foreshadowed by the Greeks, how in the Greek mythology Apollo, the god of light and giver of life, was also the god of medicine, and bestowed on his favorite son, Aesculapius, the divine gift of healing. The association between art and medicine, thus begun, had been carried on in some of the works of the greatest artists, of which he proceeded to give examples. He began by showing some representations of deformities in sculpture—in the gargoyles of cathedrals, for example—and then passed to the innumerable examples in mediaeval painting of devil-possession and exorcism. People in the throes of such possession had been depicted by Raphael and many another with more or less truth to the recognized picture of hysterical epilepsy. He commented upon the extraordinarily widespread and long-standing prevalence of the idea of an interior "not ourselves." Indeed, one found

the same thing in Socrates, with his "divine sign," and Joan of Arc, with her "voices," not to speak of Sir James Barrie's "McConachie" or the Irishman's "Eimagan." The idea of "somebody else inside us" went right through the art of the Middle Ages. No testimony in a law court to-day was more confidently advanced and more unquestioningly accepted than the testimony in old time as to spirit-possession. It was vouched for by troops of witnesses. People said on oath and under torture that they had actually seen the evil spirits which Rembrandt and other artists grotesquely represented as being exorcised from the head or out of the mouth or fleeing the church. Even from far-away Peru he was able to show the representation of a female skull which had evidently been subjected to primitive trepanning for no other purpose than to allow of the escape of the evil spirit.

Next came a series of studies of emotional expressions, including some by Sir Charles Bell, one of the greatest artists that the profession of medicine had produced. This series naturally included Reynolds's famous picture of John Hunter in reverie. Another example was "The Ecstasy of St. Jerome," in the Louvre, which the lecturer declared to be the picture that, of all others, had the greatest effect upon himself, nothing in the world spiritually did him so much good as to spend a few moments on every visit to Paris in contemplation of that work. (We are bound to say that the black-and-white reproduction which he showed had nothing of this quality, and appeared indeed to be rather repulsive, but the lecturer said that, having seen the original, he could see its beauty in the inadequate reproduction.) He concluded with a few pictures showing how artists depicted diseases, among them achondroplasia. Curiously enough, the achondroplasia was invariably represented as being in charge of animals. Then there were such deformities as club-foot, a drawing of which was found at Luxor dating from 2500 B.C. Chronic rheumatoid arthritis existed in Egypt very badly, said the lecturer, in the period of the dynasties. Hydrocephalus and acromegaly were other abnormalities represented in art. Rodent ulcer was depicted in one of Albert Dürer's engravings, dated 1502. A delightful picture was one by Franz Hals, showing the operation for removal of sebaceous cyst from the scalp. The expressions of both patient and surgeon were eloquent, the patient in extreme apprehension, while the surgeon took the proceedings with quite phenomenal calm—very unlike Astley Cooper, who removed a sebaceous cyst from the King's scalp, and spent the ensuing days in a dreadful state of anxiety lest anything should befall the royal patient. In the Franz Hals picture, by the way, the doctor's diploma is shown hanging on the wall, and, to make matters doubly sure, the surgeon was wearing a replica of it in his hat! Sir Berkeley Moynihan concluded by saying that the medical man, visiting galleries abroad or at home, could, from his professional knowledge, find much to interest him in the details of many pictures which were not apparent to the ordinary public. Moreover, as he had said at the beginning, the contemplation of beautiful things did help him in his daily work, and it was well for every devotee of Aesculapius to turn aside now and then and worship at the shrine of his father, Apollo.

Sir Ewen Maclean, who presided at the lecture, and Dr C. O. Howthorne both expressed the thanks of the gathering to the lecturer, the latter remarking that what Sir Berkeley Moynihan had said about the use of leisure for the study of art filled him with a certain sadness at his own wasted opportunities. In responding to a vote of thanks, Sir Berkeley Moynihan said that it had been a privilege to give the address to an audience so attentive. It seemed to him that the big and important concerns in one's life, which might be likened to the bricks in a wall, needed to be held together by something scarcely visible, the mortar filling the interstices. These things, these

interests, of which he had been speaking that evening, were the mortar between the bricks. Surgery was not merely a craft or a science, it was something bigger and better than either or both. It was a spiritual devotion, and in order to set it forth as an example recourse must be made constantly to some spring or well of refreshment. That was why he had rejoiced in the opportunity that evening, not so much to show pictures or to tell more or less trivial tittle-tattle, but to put into the minds of his colleagues in the profession that this way of refreshment was open to them.

The Pathological Museum

The spacious library at University College was not too large to house the extensive and varied collection of exhibits which formed the Pathological Museum. Almost every branch of medical science was represented, and there can have been no visiting members, whatever their specialized interests, for whom the exhibition held nothing new and instructive. It is only possible to mention specifically a few of the individual exhibits in my short account of so large a collection. Morbid anatomy naturally took the foremost place, being represented both by mixed collections of bottled specimens, contributed chiefly by the Department of Pathology and by the Surgical Unit of the Welsh National School of Medicine, and by series of specimens of the same organ designed to illustrate variations in a single pathological process. In this category the organs treated were the stomach, the heart (from the point of view of coronary disease), the gall-bladder, and the appendix. The stomach received perhaps even more than its fair share of attention, no fewer than three contributors—Professor Dible, Mr C. A. Joll, and Mr J. B. Haveraft—showing specimens illustrating peptic ulcer and its sequelae, and carcinoma. A remarkable feature in the section dealing with coronary disease was a series of skiograms of injected hearts prepared by Dr C. B. Perry, showing the changes in the vessels occurring in related patients exhibiting familial coronary disease. Specimens in some of these categories were accompanied by histological sections, and an interesting controversial note was struck in the nomenclature of renal tumours, as also in the series of sections of bronchial new growths shown by Dr J. B. Duguid, illustrating varieties of structure from a squamous to an apparently sarcomatous type. Radiology was the subject of five exhibits, four consisting of miscellaneous skiograms, and one, by Dr Lambert Rogers, confined to the appearances of spinal lesions, especially after lipiodol injection. "Foreign bodies" found a considerable place in the museum, the most notable collection being that of Dr D. R. Paterson, consisting of objects in great variety removed from the upper air and food passages, including the first recorded series of foreign bodies removed by operation in this country, amongst these being a fish hook, the removal of which is still believed to be unique. As a curiosity perhaps none of these equals the forbidding black boulder inserted by a male patient into his rectum for reasons and by means unstated, and removed with difficulty by midwifery forceps, with a fatal result. Another rarity must surely be the large leukaemic spleen, removal of which is said to have been followed by recovery. Much interest was excited by Dr Hilda V. Cunningham's living tadpoles, illustrating the effects of feeding with functionally distinct portions of thyroid gland. An exhibit of no little topical interest was the brain of a bilingual Welshman, who after abscess formation and softening of one side of the brain, remained able to speak only Welsh! Pride of place was finally taken by a long series of memorabilia of Lister, presented to the Welsh National School of Medicine by the Wellcome Historical Museum, and ranging from documents and photographs to apparatus and original antiseptic solutions used

by Lister himself. The organizers and exhibitors are alike to be congratulated on the success of the museum, which will be memorable for the range of its subjects and for the excellence of its individual exhibits.

History of Medicine in Wales

In the National Museum of Wales at Cardiff an interesting little exhibition had been gathered together for the purpose of illustrating the history of medicine in the Principality, various manuscripts, charms, remedies, and other objects having been selected from the National Library, the National Museum, and the Cardiff Public Library. Specimens of "hydrophobia stones" were shown, these were composed of a kind of alabaster, and scrapings of them were mixed with milk and drunk by those who had been bitten by dogs and cats. The owner of one of these stones knew a man who, after a lile, about the year 1850, "meowd" like a cat, and was not relieved until he had received a dose of the medicine. The "Laws of Hywel Dda," in the tenth century, prescribed the status of the doctor, who was one of the officers of the royal household. He received his linen from the queen and his woollen cloth from the king. He had to attend all within the court gratuitously, except in certain emergencies, for which he received ninenpenco and his food, together with the "blood-stained clothes" of his patient. His "sarhad" (in English "insult") was six kine and sixpence in silver, his social value was estimated at six score and six kine. One portion of the Laws dealt with the value of the members of the human body. Thus the value of a finger was one cow and twenty pence. The organs of generation were equal to one-half of all the organs, as also was the tongue, which must have rendered computation occasionally difficult after an aggravated assault. The exhibition included the text of the "Meddygon Myddfai," to which the President alluded in his address, containing the medical lore of the twelfth century physicians of Myddfai in Carmarthenshire. A fifteenth century manuscript on vellum consisted of a Latin translation of *Almansor*, a popular Arabic medical work. The manuscript showed very fine workmanship, being rubricated throughout, and with an illuminated capital letter at the beginning of each of the ten books. In connexion with this exhibition at Cardiff it is interesting to note that the directors of the Wellcome Historical Medical Museum have announced the publication shortly of a book on the history and lore of Cymric medicine. It was hoped that this work would be ready in time for this year's Annual Meeting, but the contributions of historical interest which are still being received have made it necessary to delay publication.

THE STOCKHOLM CONGRESS OF RADIOLOGY

THE second International Congress of Radiology met this year in Stockholm under the presidency of Professor Gösta Forssell. The proceedings opened on July 23rd and lasted for four days. The importance of this congress is shown by the following points. In the first place, nearly 1,000 enrolled as members, and these were drawn from thirty-nine different countries, with ladies and others the total number interested in the congress amounted to 1,500. The meeting was treated in Sweden as one of national and municipal importance, and the congress meetings were held in the House of Parliament, which the Government lent for the purpose, the neighbouring streets and important buildings were befagged. H.R.H. the Crown Prince of Sweden declared the congress open in an admirable speech delivered in English. This meeting was held in the large concert hall, and opened with a speech from the president. The Prince stayed on to hear several of the opening papers, and also attended some of the section meetings. A badge and chain of office was presented at the opening meeting by

the British radiologists. Mr Thurstan Holland thanked, on behalf of all the foreigners present, His Royal Highness, the chancellor of the Swedish Universities, and the president and board of management of the congress. In the afternoon the members and then friends were entertained at the palace by the King and Queen. On the following evening the municipality gave a banquet and ball in the magnificent town hall, 750 guests attended the dinner, at which Professor Kaye made an eloquent speech, which was much applauded. Later on, close on 2,000 attended the dance which took place in the famous Blue Hall. The organization of the congress was wonderfully carried out. All publications were printed in French, German, and English. Abstracts of all the papers, some 250 in number, were supplied to each member, and also a book containing the portraits, etc., of those registering. One of the notable communications was a paper, read by invitation by Dr Robert Knox, on "The rationale of radiation therapy", this drew a large audience. Professor Forssell's demonstration of cases showing the after-results of radium and x-ray therapy illustrated in a remarkable manner the success of this kind of treatment in malignant disease. A further feature of the congress was the exhibition of instruments, etc. A notable exhibit was that of the British manufacturers, who arranged a joint show. The next congress will be held three years hence in Paris, under the presidency of Professor Beclère.

PARATYPHOID FEVER IN HERTFORDSHIRE

THE outbreak of paratyphoid fever which occurred in Hertfordshire during the closing quarter of 1927 is well set forth by Dr W. V. Shaw of the Ministry of Health in a report¹ just issued. The district affected includes the borough of Hemel Hempstead and the rural districts of Hemel Hempstead and Watford. Between October 23rd, when the first cases sickened, and December 29th, when the outbreak terminated, the total cases were 166. The number of cases week by week during the six weeks of prevalence were 8, 86, 56, 14, 1, and 1. The peak of the epidemic was on November 4th, when 28 persons fell ill. The curve declined more gradually than it rose, presenting a positive skewness. Though no deaths took place, the type was not wholly mild. Many of the early cases were considered to be influenza, but the blood of almost every patient was subjected to Widal's test, with positive results to *Bacillus paratyphosus B*, and the same organism was demonstrated in the urine and faeces of a number of cases. The clinical manifestations varied. The onset was often abrupt, especially in children. Some attacks began with epistaxis, followed by headache and anorexia. Many had sore throat and general malaise. Some had laryngitis and bronchitis, and a few pneumonia. Diarrhoea was not a constant feature, and many suffered from constipation. Intestinal haemorrhage was not infrequent. Three cases had severe abdominal pain suggestive of appendicitis, and one operation was performed. Some had an early skin eruption resembling scarlet fever, which later developed into rose spots, a quarter of an inch and more in diameter. Pyrexia was intermittent, and hyperpyrexia up to 105° F. occurred. Several cases had relapses. The mild attacks with little constitutional disturbance made the outbreak difficult to deal with, and it is probable that in a number of instances no medical advice was sought. In early stages, before the significance of the outbreak was realized, a number of the sick were treated at home. Dr Shaw pointed out that in the interests of all concerned all patients fit to be moved should be admitted to hospital. The stress of the arrangements fell upon the committees of the joint hospitals, and

¹ Ministry of Health Reports on Public Health and Medical Subjects, No. 63. H.M. Stationery Office, 1928. Price 3d. A preliminary account of this outbreak was given in the *British Medical Journal* of November 25th 1927 p. 1002.

beds were freed for the reception of the sick, not only in the Hemel Hempstead and Watford Joint Isolation Hospitals, but also in the West Herts General Hospital, and, the necessary sanctions having been obtained, in the Hemel Hempstead Poor Law Infirmary. The distribution of cases was limited to a well defined area in the situation stated, and the only factor common to the persons infected, as inquiry showed, was the delivery of milk to them by a retailer whose premises were in Hemel Hempstead borough. The retailer obtained his milk—170 gallons daily at the date of the outbreak—from eleven sources, collecting it in the farmers' churns by means of his own motor. He cooled it on his own premises, and distributed it in cans. Of twelve persons who took part in the retailing no fewer than seven figured as cases of paratyphoid, but in the times of their sickening they did not antedate the general outbreak, and could not be held responsible for it. Dr Shaw therefore followed the line of milk supply a stage further back. He investigated the eleven farms from which the milk was derived. Ten were blameless, but at one he found that the farmer's wife had been ill early in October, and one of his children later in the month. The wife admitted illness with reluctance, one of her symptoms had been diarrhoea. In the case of the child a doctor was called, he diagnosed broncho-pneumonia. Dr Shaw advised the removal of both wife and child to isolation hospital. The faeces of both, on bacteriological examination, contained *Barillus paratyphosus* B in abundance. The farmyard was ill drained, a pail closet was in use. The cows coming in for milking plashed through slop water from the house. The milk strainer was defective the wire gauze was lost and replaced by butter-cloth. Dr Shaw found the butter-cloth hanging on the clothes line along with domestic garments. Under these conditions two persons suffering from paratyphoid fever were resident in the farmhouse, one of them engaged in nursing the other, and at the same time washing the milk utensils, cooling the milk and occasionally milking the cows. It seemed as though every precaution had been taken to ensure infection of the milk, which took place with the results recorded.

REDUCTION OF FRACTURES UNDER LOCAL ANAESTHESIA

THE best results in the treatment of fractures are only to be obtained after the displacement of the fragments has been corrected, but such correction is often prevented by the reflex muscular spasm or the pain which manipulation causes. In a recent paper in the *Journal of the American Medical Association*¹ Dr Carl O. Rice of Minneapolis advocates the use of local instead of general anaesthesia for the immediate reduction of fractures of the lower part of the forearm. The objections to inhalation anaesthesia in emergency cases are well known. Chief among them is the unpreparedness of the patient, who may not have the empty stomach which is indispensable for the administration of chloroform or ether, and preferred for the inhalation of nitrous oxide gas. Dr Rice says that at the Minneapolis General Hospital fractures of the forearm are seen almost every day, so that a fair field is there offered for a trial of new methods or of old methods revived. As long ago as 1885 J. R. Conway, jun., advocated the use of cocaine as an anaesthetic in fractures and dislocations in an article published in the *New York Medical Journal*, but although that drug or one of its substitutes has been employed for this purpose here and there ever since, its use has not become general. As already stated, Dr Rice has found local anaesthesia very useful in a well-equipped general hospital, but it seems probable that its advantages will be still more evident to the general practitioner, who must often have to deal with

Colles's or other fracture of the forearm single-handed without skilled assistance, in circumstances which preclude the use of a general anaesthetic. To all such the precise directions which are given in Dr Rice's paper should be valuable. The method he favours is that of circular conduction anaesthesia, whereby all afferent stimuli are cut off from the sensorium by a zone of procain (novocain) hydrochloride injected close to the bone. The solution recommended is of the strength of 1 per cent, containing "one drop of epinephrine solution per drachm." In the case of the radius—which alone is dealt with in this paper—the whole circumference can be injected through two punctures, by one of which the anterior and outer surfaces can be reached and the posterior surface by the other. It is obvious that the ulna could be anaesthetized with equal ease by a similar procedure. Some 4 or 5 c.c. of the anaesthetic solution is also injected below the fractured surface of the bone. The amount of 1 per cent procain hydrochloride solution used has varied in the cases reported from 15 to 60 c.c. Generally speaking, Dr Rice prefers the smaller quantity, which should be sufficient to produce anaesthesia without obscuring the bone-ends by swelling. Thirty minutes is allowed for the anaesthetic to take effect. Should, however, a second manipulation be found necessary the injection should not be repeated until several days after the first one, for, owing to swelling, it is unlikely to be effective. The ease with which reduction is effected is said to be surprising. So far Dr Rice has treated fifty cases in this way, seven of which are reported in full, including fractures of both bones, as well as typical cases of Colles's fracture and of displaced epiphysis. There is nothing very new in this method, but it is as well that attention should be recalled to it, for it is simple, safe, and efficacious.

REPORT OF THE MINISTRY OF HEALTH VACCINATION COMMITTEE.

IN February, 1926, a committee was appointed by the Minister of Health, in conjunction with the Medical Research Council, to consider matters relating to the preparation, testing, and standardization of vaccine lymph, the practical methods available for diminishing or removing any risks which may result from vaccination, the most appropriate methods of vaccinating in epidemic and non-epidemic periods, and to co-ordinate investigation of these questions in this country and abroad. We have just received the report¹ of this committee, to which further reference will be made in a subsequent issue. One or two outstanding points, however, deserve mention at once. The pathology of encephalo-mylitis occurring in the course of virus disease and the exanthemata was discussed in the Section of Pathology and Bacteriology at Cardiff on July 25th, and a summary appears at page 202. It is therefore interesting to note that in the report just issued it is stated that the available evidence acquiesces vaccine virus of being the sole cause of encephalitis, though vaccination cannot be exonerated from playing some part in its etiology. The committee declares its belief that "the co-operation of vaccine with the viruses of poliomyelitis or of encephalitis lethargica, or possibly some unknown neurotropic virus harboured by a vaccinee must for the present be retained as a working hypothesis of causation pending further research into the nature and properties of neurotropic viruses in general." Among the recommendations is one that in order to promote the acceptance of vaccination the customary four insertions of vaccine should be replaced by one and that multiple scarification should not be used, though vaccination by multiple insertions should be made available for those who desire to obtain at one operation the maximum protection against small pox.

PARENTHOOD AND BIRTH CONTROL.

IN reviewing, in the *Journal* of March 12th, 1927 (p 475), a book entitled *Medical Views on Birth Control* we concluded by recommending it to "all those, medical or lay, who wish to be acquainted with the facts and to be helped to form a reasonable opinion upon a very difficult and important subject." The final conclusion of all the distinguished medical writers whose essays composed that book was adverse to the practices about which they had been arguing. We think it right, therefore, to direct attention to another booklet by a medical man, whose identity is properly undisclosed, entitled *Parenthood Design or Accident?*¹ in which the opposite conclusion is heartily commended, but in regard to which we can with equal sincerity use the words quoted above. There is a preface by Mr H G Wells, in which he says of the book that "it is written extremely clearly and well," that it is "right-minded and well done," that it is "never vague, sloppy, lyrical, nor shamefaced." Whether its thesis be accepted or not, there may be general agreement that these commendations are not undeserved, and it may be agreed further that "people who do not want to practise birth control—and some very good reasons exist for restraint in its employment—people particularly who want to oppose it altogether ought to possess the minimum of lucid knowledge here conveyed." The booklet or pamphlet is, in fact, the most moderate, clear, and useful presentation of the case for birth control that we have seen. It is published under auspices which seem to be directly or indirectly associated with the Labour Party, but while its special appeal is evident this does not really vitiate the exposition or the argument, except in so far as the last few pages are concerned with the internal question of whether that party should come to a definite official decision on this subject. The statements of the book are so logically made throughout that it may be worth while to point out two or three instances in which the full consequences of the arguments are just shirked, or in which certain of their bearings are avoided. The author deals with the suggestion that the use of contraceptives may result in the production of sterility, and he properly asks for evidence, especially for statistical evidence, that in fact it does so. He triumphantly concludes with the statement "There is no evidence that birth control produces sterility, no couple need be deterred from practising birth control for fear that it will prevent them having children when they want them." He cannot, however, properly stop there, his conclusion is not established, his case at the best only half proved. It is equally incumbent on the supporters of birth control to produce the statistical data required and to show from them that sterility is not so produced. In the absence of such evidence the proposition that sterility must be produced, or is usually produced, by the prolonged use of contraceptives is not proved. It remains equally true that this may be the case, and therefore the fear of it cannot confidently be dismissed by those practising methods for the control of conception. Again, dealing with the argument that a wide knowledge and practice of these methods would lead to men and women becoming "less restrained in the expression of their sexual desire," and so to increased illicit intercourse, he replies that conduct is not virtuous when it is produced by fear. "There is no virtue in refraining from sexual intercourse through fear of undesired consequences." Even this may be arguable, but should the soundness of the argument be admitted on the ethical plane, it can scarcely be admitted on the social, for, except in certain communistic circles, an increase in illicit sexual intercourse would admittedly entail un-

desirable consequences. Further, there seems to be some inexactness as to what is disallowed by authority in county or municipal maternity clinics. "In this matter all help or information is taboo" is the statement, but while it is true that any general teaching or demonstration of birth control methods is forbidden, it does not appear that advice on this matter in individual cases in which it is medically justified would be interfered with. In a book of the general character of that under review it is a pity to discover any overstatement of its case. The best advice we can give is that both the publications mentioned in this note should be read together.

DIRECT REPRESENTATION ON THE GENERAL
MEDICAL COUNCIL.

ON Monday, July 23rd, the Representative Body of the British Medical Association adjourned at 12.30 p.m. to enable the representatives of English and Welsh Divisions to hold a special meeting for the selection of two candidates at the forthcoming by-election of direct representatives on the General Medical Council. It will be remembered that on receiving notice of the vacancies caused by the death of Dr J A Macdonald and by Sir Robert Bolam's resignation of office as direct representative on his nomination to represent the University of Durham, the Medico Political Committee circulated a notice to all Divisions in England and Wales advising them of the vacancies and requesting them to call meetings of the whole profession in their several areas for consideration of the matter. The list of nine names presented to the special meeting of English and Welsh representatives at Cardiff was the result of the nominations received from these meetings of the profession. The representatives themselves were instructed by the Divisions as to their vote, and the two candidates chosen, Drs J W Bone and E K Le Fleming, will in due course be put forward as the Association's candidates at the by-election in October.

FOOT AND MOUTH DISEASE.

THE third progress report¹ of the Foot-and-Mouth Disease Research Committee has just been issued. Owing to the pressure upon our space this week in consequence of the Annual Meeting more than a brief announcement is not possible, but we hope in an early issue to consider the report at greater length. This Committee, which was appointed in 1924, published its second progress report rather more than a year ago, and in referring to it on March 5th, 1927 (p 438), we expressed the hope that the time would come when the eradication of this scourge would be by means of the hypodermic syringe rather than the pole-axe. The present report indicates that some slight advance in this respect can be recorded, though, unfortunately, the virus—whatever its nature—seems to have very little ability to immunize for longer than about six months. It is now possible, however, to distinguish between an animal which has recovered from an attack and one which has not suffered, this suggests that the way may be opening for more efficient methods of controlling the infection.

THE contributors to the Fernier Memorial Fund met on July 18th under the chairmanship of Sir Charles Sherrington, and resolved to invite the Royal Society to accept the sum of £1,000 in trust to found a David Fernier Memorial Lecture. It was further decided that the balance of the fund shall be applied as seems best when the total contributions are known. The fund will be closed on September 30th. The honorary treasurer is Dr W Aldren Turner, 18, Harley Street, W 1.

LEAD TETRA-ETHYL IN MOTOR SPIRIT

INTERIM REPORT OF THE COMMITTEE OF INQUIRY

THE Departmental Committee on Ethyl Petrol, appointed by the Minister of Health on April 2nd to inquire into the alleged danger to health arising from the use of this type of motor spirit, issued an interim report¹ on July 27th, in which it is stated that the Committee has concluded that there are no reasons for prohibiting the use of ethyl petrol, so long as certain precautionary measures are maintained. The terms of reference of the Committee were as follows:

To inquire into the possible dangers to health resulting from the use of motor spirit containing lead tetra-ethyl or similar lead containing compounds and to report what precautions, if any are desirable for the protection of the public or of individuals in connexion with the use or handling of such motor spirit.

Sir Frederick Willis, who was until recently chairman of the Board of Control, is chairman of the Committee, which is composed of the following members:

Departmental Representatives—Ministry of Health: Sir George Buchanan, G.B., M.D., Home Office; Dr J. G. Bridge, F.R.C.S. (Senior Medical Inspector of Factories); Air Ministry: Mr D. R. Pyc, M.A. (Deputy Director of Scientific Research); Medical Research Council: Sir Charles J. Martin, C.M.G., D.Sc., F.R.S.; F.R.C.P. (Director of the Lister Institute); Government Chemist: Sir Robert Robertson, K.B.E., D.Sc., F.R.S.; War Office: Major W. R. Galway, O.B.E., M.C., M.B. (Director of Experiments in the Chemical Warfare Department); Department of Scientific and Industrial Research: Dr C. H. Lander, D.Sc. (Director of Fuel Research).

Non official Members—Mr A. Chaston Chapman, F.R.S., F.I.C.; Sir William Willcox, K.C.I.E., G.B., M.D., F.R.C.P.; Professor W. E. Dixon, M.D., F.R.S.

The Committee held four meetings in public and heard evidence from representatives of the producing and importing companies and of the United States Public Health Service, and from other authorities. The members had the advantage of a conference with Surgeon General Cumming, head of the United States Public Health Service, which during the past three years has given a considerable amount of attention to the investigation of the question now under review in this country. In their efforts the Committee had at their disposal the results of the exhaustive inquiries carried out in America by a committee appointed to determine what health hazards, if any, were involved in the retail distribution and general use of lead tetra-ethyl gasoline as an automobile fuel. After reviewing the work upon which the United States Committee based its conclusions, and considering the experience gained since the British Committee has reached the view expressed above.

Need for Precautionary Measures

The comment is made that certain safety measures are necessary, these, however, are already being observed by the vendors of ethyl petrol, which is the only motor spirit on the market containing any lead compound. The Committee expresses its general conclusions, and summarizes its work in the following terms:

Although there is no evidence to show that the use of ethyl petrol as a motor fuel involves more dangers to health than the use of ordinary petrol, we think for the time being the precautions indicated in the regulations suggested by the United States Committee are desirable. In particular we wish to emphasize the warning that ethyl petrol should be used only as a motor fuel and not for such purposes as cooking and cleaning. No regulations have actually been made in the United States as regards the distribution of ethyl petrol but careful observance of the regulations recommended in regard to notices to the public—the labelling of cans and pumps, the distribution of leaflets, and the dyeing of the substance red as an additional check against its use otherwise than as a motor fuel—has been secured by the terms of the contracts between the proprietors of the fuel and the retailers. Sales in this country are governed in the same way and we do not desire to recommend any legislative action so long as the terms of the contract are maintained.

Four sets of regulations were suggested by the United States Committee, these related to (1) the manufacture of lead tetra-ethyl and the blending of the latter with other

materials to make ethyl fluid, (2) the mixing of ethyl fluid with petrol, (3) the distribution of ethyl petrol, and (4) the ventilation and cleansing of garages, etc., irrespective of the use of ethyl petrol.

Safeguards in Mixing Ethyl Petrol

The report states that the manufacture of lead tetra-ethyl or its blending to make ethyl fluid is not undertaken in this country, but the Committee understands that its manufacture in the United States is carried out in accordance with the regulations referred to above. Ethyl fluid is imported in drums from America and is mixed with petrol at nine stations in this country. The Committee visited one of these stations and is satisfied that the precautions suggested by the United States Committee are observed in all respects, and that the arrangements are such that the health of the workers at these stations is fully safeguarded.

It is pointed out that adequate ventilation of all garages, whether or not ethyl petrol is used, is a matter of considerable importance, and that the danger from carbon monoxide in an unventilated garage is very serious.

Dealing with the events which led to the inauguration of these inquiries, the report explains that ethyl petrol consists of a mixture of petrol and ethyl fluid, the ethyl fluid being composed of lead tetra-ethyl, ethylene dibromide, and mono-chloronaphthalene. The amount of ethyl fluid added varies according to the nature of the petrol, but in no case does the amount of lead tetra-ethyl in ethyl petrol sold for ordinary commercial purposes exceed 1 part in 1,300 parts by volume, or about 1 in 650 by weight. "Lead tetra-ethyl," it is stated, "is a very poisonous substance, and its manufacture, its blending with other materials to produce ethyl fluid, and the mixing of the latter with petrol, must be carried out with very great care." The absence of due precautions at first in the manufacture and handling of lead tetra-ethyl was the cause of a number of deaths in the United States in 1924, this occurrence leading to the institution of an official inquiry in that country. These deaths, however, were in no way attributable to the use of the diluted mixture sold as ethyl petrol.

The investigations carried out in the United States proved that drivers of cars using ethyl petrol showed no definite signs of lead absorption after exposures approximating two years. In the case of garage employees and similar workers it was found that they might show evidence of lead absorption and storage, and that the amount was somewhat increased where ethyl petrol was used. The effect, however, was slight in comparison with that shown by workers in other industries where there was a severe lead hazard, and for the periods studied was not sufficient to produce detectable symptoms of lead poisoning. It was further revealed that in the regions in which ethyl petrol had been used to the greatest extent for a period of between two and three years no definite cases had been discovered of recognizable lead poisoning or other disease resulting from the use of ethyl petrol. In view of these conclusions the United States Committee reported that there were, at the time, no grounds for prohibiting the use of ethyl petrol, of the composition specified, as a motor fuel, provided that its distribution and use were controlled by proper regulations. Subsequent inquiries, which are still being continued, have not so far detracted from the validity of these conclusions.

Fear of Cumulative Effects

The fear of danger to health arising from the use of ethyl petrol is mainly due, the report observes, to the recognition of the lipid solubility and peculiar toxic qualities of lead tetra-ethyl and of the cumulative effects of lead. It is also feared by some that harmful results may occur and may not be evident until many years hence. The insidious nature of chronic lead poisoning is such that some of our witnesses have raised the question whether an experience of even three or five years would be sufficient to give practical value to a conclusion that there is no demonstrable risk. Spread over a still longer period they argue some form of lead poisoning may yet result, possibly a specific form not ordinarily associated with lead, and this possibility must be taken into account. In regard to this contention we have been impressed by the reassuring fact brought out by the United States inquiries that garage workers who have been

¹ Cmd. 3159 London: H.M. Stationery Office or through any book seller. 1928. 4d. net.

² Reports of the proceedings were published in the *British Medical Journal* on May 5th (p. 770), May 19th (p. 871), June 16th (p. 1053) and June 23rd (p. 1073).

handling ethyl petrol continuously for between four and five years, though subjected to close and frequent medical supervision, have shown no signs of lead poisoning.

Investigation to Continue

The concluding paragraph of the report indicates why the Committee has deemed it necessary to issue an interim report, and explains that, having taken this step to reassure the public, it is proposed to proceed with further investigations. The Committee states:

Having regard to the somewhat alarming statements made in the House of Lords and in the press it has seemed to us desirable to make this interim report and to publish the evidence which we have taken. Owing to the small consumption of ethyl petrol in this country it would be impossible at present to embark upon an extensive examination of human subjects, and in view of the scope and thoroughness of the investigations of this type made in the United States we consider it would be superfluous to do so. The value of such work is in proportion to the length of time it has been carried on and in this respect any investigations in this country would necessarily fall short by three years of the United States investigations, which are still being continued. We have, however, decided to make some investigations with a view to confirming certain points in the work carried out in the United States and possibly elucidating some points which are not covered by that work.

England and Wales.

Epsom College

THE seventy-fifth anniversary of Founder's Day was celebrated at Epsom College on July 28th. During the past year the five courts have been renovated, and a new one added, the swimming bath is being improved, and a system of daily disinfection has been introduced. Towards the erection of the new sanatorium more than £5,000 has been received, and it is hoped that the receipt of further donations will soon enable a start to be made with the building, the plans for which have been approved. Together with the valuable structural additions, such as the chapel, chemical laboratory, class rooms, and cricket pavilion, to which reference has been made previously in our columns during the last five years, there has been a considerable augmentation of the scholarships which enable the sons of medical practitioners to be educated at the school and to receive subsequently assistance in medical training at certain London hospitals. The headmaster, Mr. A. C. Powell, in his annual report described the outstanding features of a very good year's work. The number of successes in previous years in the London University school examinations had been surpassed, and it was clear that the already high standard of education in the College was being raised still further. A senior open classical scholarship had been won at Pembroke College, Oxford. Mr. Powell mentioned also successes in athletics and shooting and added that a very good report had been received on the O.T.C. He referred with gratitude to the substantial increase in scholarships open to Epsom boys, and notably to those made available recently at St. Thomas's and Charing Cross Hospitals. Lord Riddell, who gave away the prizes, addressed the large audience on the subject of "verities," which had not changed since the teaching of Hippocrates had defined them. They included devotion to truth, the recognition of the importance of training in observation and method, and retention of a view of the main objective, together with honesty of purpose and the use of tact. Dr. Raymond Crawford, in a brief witty speech, thanked Lord Riddell for his address. The usual cricket match with a team of old boys was a popular item of the programme, and the band of the 1st Battalion of the King's Own Royal Regiment played a selection of music. In the evening an excellent choral performance of *Iolanthe* was given by the College Musical Society.

The Interpretation of Vital Statistics.

Lord Cozens-Hardy, chairman of the St. Helens Insurance Committee on July 24th gave a report on the vital statistics of the borough for 1926, which, besides possessing considerable local interest, served to illustrate the misleading results which may follow from a comparison of 'over all' death rates for populations not identical

in age composition. He pointed out that the true relative mortality in St. Helens, as compared with England and Wales, could be ascertained only by making a separate calculation for each age, he had therefore divided the total population of 110,000 into males and females and into their respective age groups, comparing the figures with the corresponding figures for the whole country. Taking the English Life Table No. 9 (contained in the Registrar-General's Decennial Supplement last year) he then calculated the "expected" number of deaths in St. Helens for each age-group in 1926, comparing with this the actual number of deaths recorded. The result showed that the number of deaths under 5 years in St. Helens was higher than the standard (for England and Wales) by 30 per cent for males and 24 per cent for females, for ages 5 and over, males were 13 per cent and females 15 per cent higher than the standard. Lord Cozens-Hardy stated that, observing that the over-all death rate in 1926 in England and Wales was 11.6 per 1,000, and in St. Helens 12.0 per 1,000, many people had thought that the death rate in St. Helens was only about 3 per cent too high. This comparison was misleading owing to differences in age distribution, the "expected" over-all death rate in a population with the St. Helens distribution of age, if the death rate at each age were in accordance with the life table mentioned, was 10.2 per 1,000, which indicated that in 1926 the St. Helens death rates were 18 per cent higher than the rates for England and Wales as a whole. Analysing the chief causes of death in a similar fashion, Lord Cozens-Hardy stated that the male death rate from pneumonia was no less than 59 per cent above standard, from bronchitis it was 46 per cent too high, from congenital debility, etc., it was 37 per cent too high, and from tuberculosis 7 per cent too high. For heart disease St. Helens was 2 per cent, and for cancer 15 per cent, better than standard. These six causes were responsible for more than half the male deaths in St. Helens, and the male death rate from them, taken together, was 20 per cent higher than the standard for England and Wales. The figures given, the speaker concluded, did not pretend to be absolutely accurate, but they might be taken as giving a fair picture of the position.

Notification of Mentally Deficient Children

The Board of Education has issued a draft of the proposed new regulations for the notification of children under the Mental Deficiency Acts, the revision of the regulations has been made necessary by the passing of the Act of 1927, amending the Act of 1913. It is intended that the new order, the Mental Deficiency (Notification of Children) Regulations, 1928, shall come into force on October 1st. An important modification is the withdrawal of the requirement (imposed by the 1914 Regulations, now repealed) that every proposal to notify a child who is not either an idiot, an imbecile, or a moral imbecile must be referred to the Board. The regulations cover cases in which the certifying officer (the school medical officer or other practitioner appointed for the purpose) has certified that a child of 7 years or upwards is incapable by reason of mental defect of receiving benefit or further benefit from instruction in a special school or class or is mentally defective and cannot be instructed without detriment to the interests of the other children. In such cases the local education authority is required normally to notify the name and address of the child to the local authority under the Mental Deficiency Act 1913, furnishing the local authority with copies of the certificate and report of the certifying officer. In cases in which, upon consideration of the reports of the certifying officer and of teachers or others, the local education authority is in doubt as to the capability of the child, the education authority is required to refer the matter to the Board before notifying the child. If it is proposed to notify a child who is blind or deaf the case must also be referred to the Board. It is further provided that if the certifying officer reports that a child is not incapable by reason of mental defect, etc., and the education authority is satisfied that it is desirable that the child should be placed under supervision or guardianship or sent to an institution, the Board may authorize

the notification of the child. Local education authorities are instructed to notify to the local authority under the 1913 Act the name and address of any mentally defective child who, on or before attaining the age of 16, is about to be withdrawn or discharged from a special school or class, and in whose case the education authority is of opinion that it would be to his benefit to be placed under supervision or guardianship or sent to an institution. The parents of children affected by the regulations must, it is laid down, be informed by the education authority of any action it is proposed to take in this connexion.

Following-up by Almoners' Departments

The report of the lady almoner of the Royal London Ophthalmic Hospital, Moorfields, on the work of the social service department during 1927, contains an interesting account of an investigation into the results of sending certain children to the Metropolitan Asylums Board's Ophthalmic Schools at Swanley. During the years 1924 and 1925, fifty children, suffering from diseases of the cornea, conjunctiva, and eyelids, were transferred from Moorfields to Swanley. Only twelve of these children had been ill for less than six months, and some had been out-patients for years. The average stay at Swanley was seven months. After allowing a year to elapse, the almoner had each patient visited at home. It was found that 70 per cent of the patients had been cured by one period of residence at Swanley, 8 per cent relapsed but were cured by a second course, 16 per cent relapsed after three to eight months, and underwent further prolonged treatment at hospital, three of the fifty were still at Swanley at the end of 1927. Such well organized following-up of cases by almoners' departments would be of great value in other directions, such as some surgical procedures, and tuberculosis. These departments are particularly well fitted to undertake inquiries of this nature.

Ireland.

Fermanagh County Hospital

THE committee of the Fermanagh County Hospital received recently a deputation from the county Fermanagh medical practitioners. Dr Leonard Kidd, medical officer of the county hospital, stated that the hospital committee had received a letter from the Ministry of Home Affairs asking for comment on a letter of complaint which had been received to the effect that deaths of mothers and children had occurred for want of proper provision being made for their care and nursing. Dr Kidd remarked that this allegation was serious. He had read recently that the total sum spent by the district councils in Fermanagh on maternity and child welfare was £120, a very inadequate sum for the care of the fathers and mothers of to-morrow, the makers of the nation to come, in comparison with the amount spent on the care of bees and hens, on sheep dipping, on the proper raising of turnips and carrots, and the prevention of weeds. Maternity wards were urgently necessary, there was no place in the county for a woman requiring obstetrical treatment in an institution unless she became a pauper and went to the workhouse. Such a problem in Fermanagh was much more important than raising money for the provision of maternity wards in Belfast. Dr Kidd added that some of them might live to see the putting into force of the Poor Law Commission's report, but in the past many commissions' reports had been only noted and pigeon holed. He had authority for saying that the Northern Government, which had received the commission's report seven months previously, had now appointed another commission to examine it and to advise the Government. A special committee was appointed to consider the question raised by Dr Kidd.

A Hospital Patient's Injury

Judge Wakely, in the Circuit Court last May, awarded £60 in the case of Mary Mulrennan a minor suing through her father, against the Board of Health, King's County. The action had been brought to recover damages for

personal injuries sustained by the minor plaintiff while under treatment in the hospital at Tullamore for appendicitis, one of her feet, it was alleged, had been burned by a hot-water bottle placed in her bed by a convalescent patient while the plaintiff was in an unconscious condition following a successful operation. The County Health Board appealed against the decision of Judge Wakely and a reserved judgement was delivered, dismissing the appeal by a majority (Mr Justice FitzGibbon dissenting). The Chief Justice, delivering his own judgement and that of Mr Justice Murnaghan, said that arrangements were made to admit the plaintiff to the hospital, an agreement being made to whereby she was to pay 4s a week. The jury found that the defendants were guilty of negligence or breach of duty in the care and maintenance of the patient, and that the negligence was by reason of an insufficient staff. In their opinion, the jury were entitled on the evidence to hold that the hot-water bottle was negligently placed in the patient's bed, and that the absence of nurses, due to an insufficient staff, was the cause of the injury. Considering the legal consequences that followed from these facts in regard to the powers and duties of the defendants, the Chief Justice said that the plaintiff was not in the position of a pauper or poor person eligible to receive treatment as provided by the legislation giving sanction to the county scheme. The jury found that the plaintiff was received under contract to be cared for and maintained, and the Board of Health was empowered to contract for the admission of paying patients in the county home, subject to such regulations and conditions as might be approved by the Minister. The defendants had not made out allegation that they had exceeded their powers by entering into the contract or that at the time of the bargain they had exempted themselves from providing proper treatment and accommodation. At the trial of the action the defendants sought to make the case that the plaintiff must establish a statutory duty on the defendants to have sufficient nurses. For the reasons that he had stated, the duty was not a statutory duty, but was based upon express contract, there was abundance of evidence that the contract was broken, and in their opinion the appeal should be dismissed. Mr Justice FitzGibbon in his judgement, said that he could not accept the view of the facts or the law as stated in the case. The staff of the hospital had been approved by the Minister, and the defendants had no power to exceed it. There was no suggestion that the attendants were not properly qualified, and, in his opinion, the defendants had no power to contract that they would supply at the expense of the rate-payers a greater measure of accommodation to a paying patient than they had power to supply to poor persons. He could see no ground for awarding damages in this case. In his opinion the action should be dismissed.

Correspondence.

DISTRICT CO-ORDINATION OF HOSPITAL SERVICES

SIR,—It seems an immense pity to start our campaign of co-ordination and unification of hospital services by insisting that one system is the better and must therefore put the other under its heel—would it not be preferable to seek at once both the spirit and method of co-operation? I write to suggest a method which, although local conditions will vary greatly, might have some application in one district or another, or at any rate which conveys what I think must be the right outlook.

We want to keep the voluntary hospitals—both large and small—and the spirit that animates them, but we need not look far to find great work done in State departments of medicine. We have also to remember that the clinical field will have to be adequately staffed wherever it may be—whether in a voluntary, county council, or Poor Law system. Let us suppose that the co-operation, or even unification, of hospital services is decided on for some more or less self-contained district or area—say, for example,

ono of the suburbs of London. This area is likely to contain a fair-sized voluntary hospital, one or two biggish Poor Law hospitals, and a number of smaller institutions run on the cottage hospital system. The most centrally situated hospital, which for preference will be the largest of the group, should, for obvious reasons, take the bulk of the out-patient and ambulatory work, and function as a central general hospital. The smaller hospitals should retain their voluntary capacity and keep their local patriotism by setting aside some part of their accommodation for urgent local cases. With the remainder of their beds they would specialize in some branch of medicine or surgery, undertaking this specialty for the whole area. This would be their contribution to the scheme, what they gave in this way they would receive back in different departments from other special units.

So far as government is concerned, there would have to be a central governing body compounded of all interests concerned, including local practitioners, and with a general director of the service acting under it. Each hospital unit should keep its autonomy and local government. There should be a unified visiting staff for the whole area made up in the first place of the combined visiting staffs of the associated hospitals. Subsequent appointments would be made by the central body to the district hospital service, rather than to the individual hospitals. A system of rotation of nursing staffs throughout the district hospitals would be possible, so that all nurses would be fully trained. The scheme might be aided by the co-operation of local practitioners as a form of post-graduate study, and in selected cases a post-graduate medical college would have ample scope. (These points I have dealt with at length in a previous communication to the *Journal* on May 28th, 1927, p. 985.)

The question of finance is beyond the scope of this letter, and, though it is obviously a crucial point, it is of no significance in this aspect of the case, for it has to be dealt with in some way or another by whichever route we approach the subject. I am by no means convinced that such a scheme as I have outlined would be feasible or acceptable to the units, but it seems to me to put medicine and the good of the patient first, and to illustrate the spirit of co-operation and equality, rather than that of dictation. I may add that for myself I work under both voluntary and Poor Law systems—I am, etc.,

London W1, July 23rd. T H C BENJAMIN, F.R.C.S.

LEAD ETHYL PETROL

Sir,—The Departmental Committee has to-day issued its interim report, which endorses the verdict of the United States Committee that "there are no reasons for prohibiting the use of ethyl petrol." Thus it becomes almost certain that its final report will be similar.

Now does it follow that because careful expert inquiry can find no evidence of insidious damage to the public health resulting from lead ethyl petrol that no deterioration of health has resulted, or will do so? I think not, and for these medical reasons:

1 Ordinary lead poisoning can be recognized by the characteristic blue line, dropped wrist, and colic which it produces. Lead ethyl, being non-ionized, seldom or never causes these symptoms, but has an affinity for the nervous system. Severe poisoning can be recognized (by an expert) by stippling of the blood cells and by its effects on the nervous system, but for the detection of mild poisoning or slow cumulative deterioration of health there appear to be no tests available for doctors. The comforting statement that "no evidence of evil effects are to be found" is therefore valueless and misleading.

2 Doctors experienced in the old form of lead poisoning know its insidious cumulative effect, and will be very hard to convince that habitual inhalation of small doses of vaporized lead in garages and crowded streets is free from deleterious effects on our tissues, even if we cannot detect them by our present crude methods.

3 It is like the old fallacy—not yet extinct—that because an expert cannot detect consumption in a patient with the tests available we are entitled to say it is not there. We

know that it always exists (in a very curable stage) months before it makes recognizable noises in the lungs. It becomes a matter of definitions. If consumption is defined as a disease which makes noises in the lungs it is logically correct to deny its existence till it can be heard, though this attitude still sacrifices hundreds of lives. Similarly, if it is denied that lead ethyl poisoning exists till it can be recognized clinically, the reasoning is logical, but the public health will suffer in consequence of this lack of common sense. Recently I saw a man who for twelve years had been steadily inhaling silica dust at his work. For many years (probably ten) the slow poisoning would have been unrecognizable clinically, and yet it caused his death in thirteen years.

The matter is not only one of analysis and definitions, but also tests our sense of values. Are we to put a higher value on a slightly increased efficiency of our engines than on a certain—even if slight—impairment of the health, efficiency, and longevity of our exquisite bodily machinery? Even the prophetic vision of the author of *Erewhon* failed to anticipate the folly to which their idolatry of machinery would lead mankind. He would laugh (or weep) to see them feeding their engines with a deadly though diluted poison, and inhaling the gaseous excreta in garages and in the tall stagnant streets of their human ant-heaps.

Whether intentionally or not this interim report will serve as a kite by which the Government will judge which way the breath of public opinion blows. Whether they will accept lead ethyl with mock indifference or with blasts of indignation strong enough to compel its exclusion from this country (save perhaps for aeroplanes).

I believe that organized medical opinion is the last ditch in our defence against invasion by this diluted poison. It is part of the training of doctors to examine new discoveries (and the reports of experts on them) in the light of common sense. They know very well that lead in the system is not good for anyone, and that if let loose on an ignorant, careless public lead ethyl petrol will do harm, however many precautionary leaflets are printed. They alone know their powerlessness to diagnose mild poisoning by lead ethyl, and they should be consulted on the matter.

May I therefore venture to suggest that organized medical opinion (preferably the British Medical Association) should at once appoint a committee to scrutinize the evidence as it becomes available, so that when the final report of the Departmental Committee is issued they may possibly be able—without challenging the results—to point out that the clinical and medical aspects of this problem do not coincide with the scientific verdict? Thus it would sound almost stultifying for a Departmental Committee to report, "We find no evidence against lead ethyl petrol, but we nevertheless advise its exclusion from this country." But in the light of what I have written a medical committee would very possibly report in this sense—I am, etc.,

Hull, July 27th.

F C EVE, M.D., F.R.C.P.

HAEMATURIA AND INSULIN

Sir,—The apparent rarity of haematuria occurring in diabetic patients under insulin treatment is noted by Lawrence and Hollins in the *British Medical Journal* of June 9th (p. 977). The following case shows some points of contrast with the cases there detailed.

A boy, aged 5 years, was admitted to the Midland Hospital for Sick Children in April 1928. There had been no illness except chicken pox and measles at 2 years of age until two months before admission when he became poorly, lost weight, and had polyuria with glycosuria.

On admission on April 17th he was noted to be moderately wasted and had a strong odour of acetone. The urine contained 1.7 grams per cent of sugar, and gave a strong reaction for ketones. The blood sugar was above normal. There was no albuminuria or other abnormal urinary constituent. There were a few carious teeth but the tonsils were small and clean. There was no evidence of infection. His progress in hospital was very good, and his diabetic state was well controlled by dieting and insulin. Apart from the first twenty-four hours in hospital when he had 20 units of insulin he never had more than 10 units of insulin in twenty-four hours. On May 8th he was able to take an adequate diet without insulin. On May 10th the urine remained sugar free, but there was a slight positive Rothera's test. He had commenced to get up.

On May 11th at 8 a.m. whilst in bed the boy had profuse haematuria the urine being copious and heavily loaded with

bright blood. There were no symptoms or signs otherwise. The temperature (as usual) was quite normal. There was no renal or vesical pain or tenderness. The urine was moderately acid to litmus, contained a cloud of albumin, and no sugar. A slight ketosis was present.

Microscopically, there were very numerous red blood cells, but no epithelial or blood casts. Successive specimens of urine passed during the day showed a rapid progressive diminution in the amount of blood in the urine. At 6 p.m. on the same day the specimen was practically normal to the naked eye, but a haze of albumin was present together with a few red blood cells. The blood pressure was 105/60.

Two days later the urine was quite free from albumin, and no abnormal elements were present microscopically. The boy went home a few weeks later, and no further haematuria occurred.

The points of peculiar interest in this case are (a) That the haematuria was extreme but of very short duration (b) The rapid return of the urine to the normal (c) The haematuria occurred two days after the last dose of insulin (d) There was at this time only a slight ketosis.

I do not propose to discuss the true relationship of the haematuria, but I thought perhaps the former writers and their critics might be interested in the case. In accordance with Dr Lawrence's remarks the benign nature of the urinary abnormality is apparent also in this case—I am, etc.,

Birmingham.

A V NEALE

THE MECHANISM OF BLACKWATER FEVER

SIR,—I was greatly interested in the recent communication by Professor D B Blacklock and Dr G Macdonald, in the *Journal* of July 28th (p 145), which makes it perfectly clear that sarcolactic acid by its haemolytic properties and its production in blackwater fever is closely connected with the mechanism of the disease. It is obvious, however, and thus in spite of the arguments brought forward by these authors on page 147 that sarcolactic acid by itself does not account for the precipitation of blackwater fever by quinine. In this latter case I have shown¹ that urines of thirteen cases of blackwater fever examined by me contained large quantities of a strongly haemolytic disintegration product of quinine to which I have assigned the name "haemoquinic acid." Like sarcolactic acid, haemoquinic acid is normally present in the organism (after the administration of quinine), but only in very small quantities, the ratio found being

Haemoquinic acid in blackwater fever urines	578
Haemoquinic acid in malarial urines	1

The production of haemoquinic acid in large quantities in blackwater fever thus accounts as much for the haemolytic phenomena of this fever as does sarcolactic acid. Like sarcolactic acid, haemoquinic acid is an oxidation product, the latter being derived from quinine through the fission of the two nuclei A and B. This process takes place between the two carbon atoms α and β , and is followed by oxidation, the α carbon atom being oxidized to a carboxyl group

However, the production of haemoquinic acid from quinine is of a highly specialized character, which is probably subordinated in the case of malaria, since quinine when oxidized by administrations in animal experiments,² by emulsions from guinea-pig and ox liver,³ and by hydrogen peroxide,⁴ only yields quinine, no haemoquinic acid being produced. Here the oxidation proceeds

on quite different lines, the two γ and δ carbon atoms and not two α and β carbon atoms being attacked.

These specific oxidizing properties of the organism prone to blackwater fever are probably due to specialized oxidases, the action of which may be described as an idiosyncrasy, but which have to be taken into consideration. They form, in my opinion, a very important factor in the mechanism of blackwater fever if viewed either from the point of the formation of sarcolactic acid or from that of haemoquinic acid.

May I, in conclusion, be permitted to quote from Sir David Bruce? In a letter to me, dated April 8th, 1919, Sir David wrote as follows: "Blackwater fever is one of the most interesting conundrums. I suppose as knowledge grows light will be thrown upon it, and I hope that your haemoquinic acid is a particularly bright streak." The discovery of sarcolactic acid as applied to blackwater fever by Blacklock and Macdonald is such a bright streak—I am, etc.,

M. NIERENSTEIN, Ph.D., D.Sc.,

July 30th.

Lecturer in Biochemistry in the University of Bristol.

"ACTIVATED" FLUORESCIN IN INOPERABLE CANCER

SIR,—Will you kindly afford me the opportunity of removing a misconception which might arise in connexion with the brief reference to my paper in your report of the proceedings of the recent International Cancer Conference? Your reporter refers to "the enhanced effect of irradiation after painting the surface with activated fluorescein," whereas in fact activation is brought about by mild irradiation subsequent to the use of the fluorescein. A 2 to 5 per cent solution of the sodium salt is employed for painting the surface in the case of external growths, and, when necessary, the drug is administered internally in doses of 30 grains of the powder. Owing to the extreme diffusibility of the salt it suffices to give it by the mouth, thus avoiding the trouble of intravenous injections.

Within a few hours of giving fluorescein internally the whole surface of the skin takes on a yellowish coloration, which disappears again after a varying interval, elimination of the drug being mainly by the kidneys. It is also worthy of mention that the application of fluorescein to an ulcerated surface causes no pain, and further, that its internal administration has not given rise to any unpleasant symptoms—I am, etc.,

Brighton July 28th.

S. MONCKTON COPPEMAN

THE GUILLOTINE AND ETHYL CHLORIDE

SIR,—In reference to the article by Mr Sandiford and Dr Clayton (*British Medical Journal*, July 28th, p 149), when a gag is inserted before induction it is not always possible with a struggling child to "hold the lower teeth tightly against the gag." I found some years ago that a small piece of rubber (rectangular, with its lower corners rounded and a slit near its upper edge through which the lower plate of the gag is passed) will stay between the lower teeth and lip, so that nipping of the latter is prevented. May I draw attention to the importance of removing loose front teeth which are likely to be displaced by the gag or other instruments?

As an anaesthetist I wish every operator would use La Forge's adenotome for the main mass of adenoids. When a guarded curette is used even by a skilful operator, the mass may escape from it or tags may be left, and one may have to restrain or re-anaesthetize the child in difficult or dangerous circumstances. The adenotome, acting like a shovel and not like a hoe, brings the central mass cleanly away in a box—I am, etc.,

London W.W. July 30th

J. D. MONTIMER

HOSPITAL PATIENTS AND DOCTORS' LETTERS

SIR,—In these days when the sphere of the general practitioner is being encroached upon in so many and various directions by infant welfare centres, school and ante-natal clinics, and the like, it is rather disheartening, and I may say alarming, to find that the great London hospitals are

¹ War Office Observations on Malaria 1919 p 68 *Journ. Royal Army Med Corps* 1918, p 220.

² Gleason and Schanmann *Arch. f. Schiff- und Tropen Hyg.* 1907 p 84, and many other papers on the subject.

³ Lipkin *Ann. Trop. Med.* 1909 p 149.

⁴ Nierenstein *Biochem. Journ.*, 1920, p 572.

accepting one's patients for treatment without the time-honoured "doctor's letter"

Within my own practice of late I have heard of this happening in several instances, and this among patients who are quite capable of paying the moderate fees charged in this country for private treatment

Whilst making this protest I should fail in my duty if I did not acknowledge gratefully the magnificent work done by the general hospitals and the great help afforded to us as general practitioners in the treatment of those cases we refer to the hospitals

Surely the British Medical Association can use its influence to protect the mass of its members from this form of attrition. Let the hospitals refuse patients who present themselves for treatment unless they bear a letter from their private medical attendant—I am, etc.,

Sutton Surrey July 26th.

Obituary

SIR ARTHUR CHANCE, F R C S I,

Late President, Royal College of Surgeons in Ireland, and Royal Academy of Medicine in Ireland

WE have to announce with deep regret the death of Sir Arthur Chance, which occurred at his residence in Dublin on July 26th

Arthur Gerald Chance was born in Dublin in 1859. He was educated at the Catholic University, Dublin, and obtained the diplomas L R C S I in 1880 and L R C P I in 1881, being admitted to the Fellowship of the Royal College of Surgeons ten years later. While still comparatively young he won an outstanding position, and in the course of his professional career held many important offices, taking a leading part in affairs connected with medical education.

He was senior surgeon to the Mater Misericordiae Hospital and consulting surgeon to a number of other Dublin institutions, including Dr Steevens's Hospital, the Orthopaedic Hospital of Ireland, the Dental Hospital of Ireland, and St Michael's Hospital. From 1904 to 1906 he held office as President of the Royal College of Surgeons in Ireland, and during his tenure of that office he received the honour of knighthood. He was an honorary Fellow both of the Irish Royal College of Physicians and of the Royal College of Surgeons of Edinburgh, and was President of the Royal Academy of Medicine in Ireland from 1921 to 1924. For two periods, from 1892 to 1895 and from 1906 to 1915, he was surgeon-in ordinary to the Lord Lieutenant of Ireland. During the war Sir Arthur held a commission as colonel in the Army Medical Service, and from 1917 to 1920 was inspector of special military surgical hospitals in the Irish Command. He was at one time a member of the Senate of the National University. For some years he represented the Royal College of Surgeons in Ireland on the General Medical Council and the Dental Board, and was a medical visitor in lunacy under the Irish High Court. From 1919 to 1924 he served as a member of the first General Nursing Council for Ireland, having previously been chairman of the Irish Nursing Board, and in 1927 he was appointed a member of the Free State Medical Council on its formation. Sir Arthur Chance found time for active interest in the work of the British Medical Association, he had been vice-president of the Leinster Branch and held office as chairman of the Dublin Division in 1903-4.

A colleague writes: The reputation which Sir Arthur Chance enjoyed in the domain of surgery might be said to be world-wide, it was certainly European. His solicitude for the interests of his great profession never relaxed, and for many years he took an active interest in all matters that affected the welfare of even the humblest of his colleagues. The citizens of Dublin and the people of Ireland generally on many occasions recognized and appreciated his sterling worth, and King Edward VII put his seal on that approval when he knighted the famous surgeon in 1905. Sir Arthur was an indefatigable worker, and his devotion to his profession was such that his services

were at the disposal of patients at all hours of the day and night. His activities were particularly in evidence at the Mater Hospital, Dublin, of which for many years he was senior surgeon, it may be said that it was mainly due to his exertions and self-sacrificing labours that this noble institution attained to the eminence which it now enjoys. No complete record could ever be made of the many charitable and devoted acts which Sir Arthur Chance performed during his connexion with the hospital. His kindness to the poor was proverbial, and no deserving subject was turned away. He might, indeed, be well described as the poor man's surgeon.

In 1886 he married Martha, daughter of the late Daniel Rooney of Belfast, who died in 1891. In 1900 he was married to Eileen, daughter of the late Mr William M. Murphy, Dарты. He was the father of eight sons and five daughters. After the death of Mr William M. Murphy Sir Arthur Chance became one of the directors of the Independent Newspapers, and displayed characteristic energy and capacity in the duties of this office. In his zeal for the development of the publications of the company he always bore in mind the welfare of the staffs, and was ever kindly and considerate in his relations with the employees. He was an unsuccessful candidate in the election for the Seanad Éireann in 1925. He seldom appeared on public platforms, but on the rare occasions when he did speak in public he was effective, terse, and interesting in his utterances. Sir Arthur's brother, Mr P. A. Chance, who pre-deceased him, was a member of the Irish Parliamentary Party from 1885 to 1894, representing the constituency of South Kilkenny. The funeral, which was private, was held on July 28th after High Mass at Westland Row Catholic Church, Dublin.

Dr JOHN RANDLE, who died at Lagos, Nigeria, on February 27th, was one of the oldest practitioners of his race in West Africa. Born in 1855, he was a native of Sierra Leone, where he became a dispenser in the Colonial Hospital, being later employed in the same capacity on the Gold Coast before coming to Great Britain. He received his medical education at the University of Edinburgh, graduating M.B., C.M. in 1888. On his return to West Africa he was appointed an assistant surgeon in the Nigeria Medical Service, and as such served with the Jebu Expedition in 1893, leaving the service soon afterwards to commence private practice in Lagos, where he was successful in building up an extensive connexion. He was a member of the British Medical Association. Dr Randle played an active part in public affairs in Nigeria, and was at one time a temporary member of the Legislative Council. He had also served on a number of Government committees. The interests of his own people engaged his attention unceasingly, and he was at the time of his death president of the People's Union and of the Reform Club. He contributed largely to the funds of the Fourah Bay College to supplement a legacy given by his friend and colleague Dr Ohadijah Johnson for the introduction of the teaching of science, while the poor of his native village in Sierra Leone were the subject of an annual benefaction. His funeral was attended by a large number of his colleagues, including Dr D. Alexander, Director of Medical and Sanitary Services, Nigeria.

Universities and Colleges.

UNIVERSITY OF LONDON

At the June matriculation examination there were 168 successful candidates in the first division and 1109 in the second division, in addition, 48 took supplementary certificates in Latin.

UNIVERSITY COLLEGE

The following awards have been made in the Faculty of Medical Sciences:

Physiology: Sharper Scholarship T. Orden. Senior Class Prize (gold medal) L. G. Norman. Junior Class Prize (silver medal) K. K. Cohen and G. F. Donkerley (equal). Organic and Applied Chemistry: General Course (silver medal) E. A. Dovenish. Pharmacology: (silver medal) D. Davidson.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE parliamentary session was ended this week, arrangements being made to prorogue the House on August 3rd till November, when a new session will begin and last into the new year. All outstanding estimates were voted, debates arising on the Scottish Estimates and those for the Ministry of Health. On the latter the Labour Party arranged to discuss slums, the administration of the Poor Law, and the position of the Welsh Board of Health.

The following bills passed through various stages in the House of Lords. On July 27th the Offices (Scotland) Bill was read a third time. On July 30th the MARQUESS OF SALISBURY moved the second reading of the Registration (Births, Deaths, and Marriages) Bill. Lord STRACHEY moved the rejection of the bill, and the debate was adjourned. The Criminal Law Amendment Bill was read a second time on July 30th, and passed through Committee the next day. On July 31st the Rag Flock Amendment Bill and the Merchant Shipping (Line Throwing Appliance) Bill were read a second time. The Marriage (Prohibited Degrees of Relationship) Bill passed through Committee.

It has been necessary to hold over a few notes on matters connected with medicine dealt with in Parliament this week.

National Health Insurance

On July 25th, in answer to Mr Hayday Jones, Sir KINGSLEY WOOD said that during 1927 £5,400 had been discounted from the accounts of chemists who supplied drugs and appliances in Wales at a cost of 29½d per insured person. It was untrue to say that the surplus which arose in Wales had been taken to meet deficiencies in England.

On July 26th Mr CHAMBERLAIN told Mr Short that he knew the East Sussex Insurance Committee had, on July 3rd, expressed the view that a practitioner should not cease to prescribe drugs which he believed to be reasonably necessary for the adequate treatment of panel patients. Mr SINOT asked whether Mr Chamberlain knew that regional medical officers had recently brought pressure upon panel doctors respecting their prescriptions, thereby limiting their discretion in prescribing medicines for panel patients. Mr CHAMBERLAIN said the duty of insurance practitioners was to prescribe proper and sufficient medicines and the interviews arranged between certain practitioners and regional medical officers were solely to secure that this duty was performed.

The Noise Nuisance

Sir W. JOYNSON HICKS, in a reply on July 26th to Sir Robert Thomas said he was aware there was much complaint, he thought with good ground, against the noise of urban streets. He had done all in his power to see the nuisance was abated, so far as that was possible by police action under present powers. He would discuss with the Ministers of Health and Transport whether anything further could be done. He had noticed that a medical authority at the recent meeting of the British Medical Association had estimated the loss in efficiency to the nation owing to these noises at £1,000,000 a week. Mr LANSBURY asked whether Sir William would communicate with the London County Council and ask them to keep their tramway tracks in order so as to prevent noise. Sir WILLIAM said he thought it would be the duty of the Minister of Transport to communicate with the London County Council.

Mr CHAMBERLAIN on July 30th told Major Edmondson that he had not received a resolution passed at the Annual Meeting of the British Medical Association at Cardiff on July 24th about the effect of noise on public health. He could add nothing to the statement made on the subject by the Home Secretary on July 19th.

Conjunctivitis among Artificial Silk Workers.—Reports from inspectors of the Home Office show according to Sir W. JOYNSON HICKS, that except in one works where the number of persons employed has largely increased the number of cases of conjunctivitis among men and women in the artificial silk industry has decreased during recent months. This industry was receiving close attention from the medical inspectors and from the general staff of the Home Office and much was being done to improve its conditions.

Proposed Cancer Hospital at Withington.—Mr CHAMBERLAIN, answering Sir Thomas Watts on July 26th said his attention had not been called to the proposed establishment of a cancer hospital in Palantine Road Withington a residential district of Manchester. Sir THOMAS asked whether, having regard to the depreciation in the value of property which would result Mr Chamberlain would set up an inquiry. Mr CHAMBERLAIN answered that if, as he assumed, a voluntary hospital was to be established, he did not know that any action was open to him.

Early Treatment of Mental Patients.—Dr VERNON DAVIES asked Mr Chamberlain on July 26th if he was aware that the only hope of reducing the incidence of insanity and improving the

recovery rate was by altering the law so as to allow and encourage the early and skilled treatment of persons mentally ill, and whether he would, at any early date, give this matter his serious consideration and take the necessary action. Mr CHAMBERLAIN said he would be sorry to think that the only hope of reducing the incidence of insanity and improving the recovery rate lay in the measures which Dr Davies suggested, but he fully realized the great importance of improving the facilities for early mental treatment and hoped to be able to take the necessary action as soon as it was practicable to introduce legislation.

Tuberculosis Mortality Rate.—Sir KINGSLEY WOOD told Sir Robert Thomas, on July 25th, that the tuberculosis mortality rate for males between the ages of 15 and 25 had been little reduced since 1910, and that for females between the same ages it had increased, but at the present time the rate for both males and females between those ages appeared to be decreasing. The Ministry of Health had considered the discrepancy between the rate of decrease in the mortality from tuberculosis in the general population and that in these age groups but the causes of this discrepancy were obscure. Investigation was proceeding, and the tuberculosis officers of local authorities would be asked to give special attention to the question.

Tuberculous War Pensioners.—Major TRYON replying on July 26th to Major Cohen, said approximately 9,000 disabled men suffering from tuberculosis were discharged from treatment with allowances during the past twelve months. During the same period 5,000 cases were admitted to treatment with allowances. The conditions under which allowances were payable had not been changed, but Major Tryon had endeavoured to secure more effective co-operation between local tuberculosis officers and the medical officers of the Ministry of Pensions in the handling of cases of tuberculosis. The arrangements for reassessing had resulted in a substantial increase in the average rate of pension.

Notes in Brief

At the suggestion of Dr Vernon Davies, the President of the Board of Trade will consult with the Minister of Health about the suggested issue of an annual report on the health of the merchant service.

Mr Chamberlain stated on July 26th that the committee which had inquired into the London Lock Hospital was considering its report. He could not say when it would be ready for publication.

Mr Chamberlain knows of no reason for revising the regulations in force concerning the treatment of casuals but officers of the Ministry of Health have been instructed to secure full compliance with the regulations.

The Scottish Board of Health has decided that the condition of the River Lochy does not warrant the local authority in calling on the proprietors to introduce a new water supply from another source.

All local authorities now provide for the medical treatment of school children.

The Minister of Health is not aware that there is any menace to the health of the inhabitants of the parish of West Thurrock from the sewage works of the West Kent Sewerage Board.

Medical News.

THE old students annual dinner of St Bartholomew's Hospital and College will be held on Monday, October 1st, at 7.30 o'clock, in the great hall of the hospital, with Sir D'Arcy Power in the chair. The honorary secretary is Sir Charles Gordon Watson, 82, Harley Street, W.

THE annual meeting of the Smoke Abatement League of Great Britain, followed by a conference, will be held in Harrogate during the week end commencing Saturday, September 29th, at the Harlow Manor Hydro. The office of the league is at 23, King Street, Manchester.

CONDUCTED visits, in aid of King Edward's Hospital Fund for London, will be made to the Tower of London on August 9th and 23rd and September 6th at 2.30 p.m. Mr Walter Bell, F.S.A., will give addresses on the Tower and conduct parties round the building. Tickets (price 7s 6d) can be obtained from the secretary of the Fund, 7, Walbrook, E.C.4.

THE Central Association for Mental Welfare has organized two courses of training each lasting three weeks and commencing on Saturday, September 8th, one is intended for persons engaged in the training of mental defectives in occupation centres, institutions, or mental hospitals, the other is for officers of local authorities and local associations for mental welfare engaged in the ascertainment and supervision of defectives. The courses comprise lectures and practical work emphasis being laid, in that for persons engaged in providing training, on teaching methods, while for others the legal and administrative side receives more attention. Hostel accommodation has been secured at the centre at which the courses will be conducted in London.

The courses have been approved by the Board of Control. Further information may be obtained from the honorary secretary of the association, 24, Buckingham Palace Road, S W 1.

AMONG the speakers at a study conference to be held at Oxford in September under the auspices of the Industrial Welfare Society, is Dr. Millais Culpin, whose subject will be 'Nervous disease and its significance in industry'—a question associated with work now being undertaken by Dr. Culpin for the Industrial Fatigue Research Board. The conference will take place at Balliol College, from September 7th to 11th, Dr. Culpin's lecture being on Monday, September 10th.

DR. EDWARD I. HOWE, barrister at law, and neurologist to the Ministry of Pensions, has been appointed H.M. coroner for the county of East Sussex.

THE Minister of Health, on July 23rd, received a deputation from the representatives of twelve metropolitan borough councils, who urged the reconsideration of letters recently issued by the Minister announcing a reduction in the Exchequer grant for the supply of milk by maternity and child welfare authorities during the present financial year. In reply, Mr. Neville Chamberlain said the reduction had been made in view of the general need for economy. In the estimates of the Ministry of Health he had come to the conclusion that there were only two possible ways in which the necessary saving could be effected, one was to stop for the time being any further development of maternity and child welfare services, and the other was to make some reduction in the grants paid for the supply of milk. He had decided without any hesitation in favour of the latter course, but he wished to make it clear that he was not insisting that local authorities should reduce their expenditure on milk. All he had done was to intimate to local authorities the maximum expenditure for this purpose which he could recognize for grant during the present year.

THE second annual report of the Manchester, Salford, and District Mothers' Clinic records that during the year the clinic has given advice to 334 new applicants making 757 since it opened in March, 1925. A statistical examination of the first 600 case papers of the clinic has shown they record 2,331 previous pregnancies, the number of living children being 1,783, showing a loss of 578, or 24.8 per cent., of all pregnancies. Nearly half of all losses were due to miscarriages of which a considerable number were definitely recorded as self-induced abortions. The hope is expressed that the newly appointed official committee on maternal mortality will give due hearing to experienced workers in birth control clinics, who, it is pointed out, have had a unique opportunity to hear the unvarnished histories of mothers.

THE forty third annual medical report of the Trudeau Sanatorium has been issued and is combined with the twenty third medical supplement for the year ending September 30th, 1927, and the eleventh collection of the studies of the Trudeau Foundation. These studies which are mainly reprints of articles published in current medical literature, include a discussion by Drs. Lawrason Brown and H. L. Sampson of the originability of intestinal tuberculosis, an account of immunity in tuberculosis by S. A. Petroff, and the report of a case of primary pulmonary mesothelioma.

THE last report of the Old Cairo and Menouf Medical Missions, Egypt, which are under the aegis of the Church Missionary Society, shows that in spite of political troubles and economic depression—which at times decreased attendance at the hospitals—a vast amount of work has been carried on at these institutions. At the Old Cairo hospital now out patients numbered 21,567 in 1926 and 21,903 in 1927, while the numbers of in patients in the two years were 8,913 and 8,644 respectively. Most of the latter were ankylostomiasis cases, 13,167 being treated in the two years. Other wise, surgical treatment accounted for the greater part of the work, 9,677 operations being performed. The smaller hospital at Menouf dealt with over 5,800 new patients in this period, while the three dispensaries, the camp hospital, and the welfare centres cared for many more. It is stated in the report that the group receives patients every year from about 1,000 villages most of these are of course, in the Nile delta, but some patients travel from remote parts of Upper Egypt and the Sudan for treatment, and a number have come from Morocco. During the past two years the organization has been handicapped by the inadequacy of the European staff, particularly at Menouf, where the work was carried on from November, 1926, to the end of 1927 without a regular European doctor. There is thus urgent need for reinforcements from England, both of doctors and nurses.

THE first Latin American Congress of Neurology, Psychiatry, and Legal Medicine will be held at Buenos Aires in the second fortnight of September, under the presidency of Professor Arturo Amigiano.

THE German Society for Diseases of Digestion and Metabolism will hold a congress at Amsterdam from September 12th to 14th, when the following subjects will be discussed: Physiology and pathology of hunger, introduced by J. Hindig of Apeldoorn, van Leeuwen of Amsterdam, Morgulis of the United States, and Determann of Wiesbaden, relations between the small intestine and diseases of the blood introduced by Morawitz of Leipzig and Nordmann of Berlin, relations between the liver and diseases of the blood, introduced by Schottmüller of Hamburg, tropical diseases and the blood, introduced by Schiffner of Amsterdam, diagnosis and therapeutical errors in alimentary diseases and their prevention, introduced by von Bergmann, Kuttner, and Berg of Berlin, and von Haberer of Düsseldorf, importance of raw meat, introduced by Friedberger of Berlin, Schennert of Dresden, and Stopp of Breslau. Further information can be obtained from the general secretary, Professor R. von den Velden, Bamberger Str. 49, Berlin, W.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication. Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1** on receipt of proofs. All communications with reference to **ADVERTISEMENTS** as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561 9562 9563** and **9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

EDITOR of the **BRITISH MEDICAL JOURNAL** *Antiology Westcott London*

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements etc.) *Articulate Westcott London*

MEDICAL SECRETARY *Mediscera Westcott London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Facillus Dublin* telephone 62550 Dublin), and of the Scottish Office 7 Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DERMATITIS EXFOLIATIVA

"W. M. B." wishes for suggestions for treatment of a case of dermatitis exfoliativa in a man over 50 years of age. It is of five years' duration. He asks if glandular treatment is of any avail in such cases and if "light" treatment has been tried with success.

ADIPOSITY OF BREASTS

"W. A. R." would be glad to have suggestions for the treatment of a lady who has marked adiposity of the breasts and abdomen. He asks if ultra violet ray treatment would be beneficial.

DRESSING FOR FISTULA

"R. T." would like to hear of a dressing suitable for the skin of the abdomen in a patient aged 72 years following laparotomy for intestinal obstruction (benign) who developed a fistula high up in the small intestine, the discharge causing intense pain and inflammation.

RATE OF FLUID ABSORPTION BY THE BODY

DR. A. H. SKINNER (Haukow) writes: Are there any experiments showing the comparative rates of absorption of fluid injected under the skin and into the peritoneal cavity? The fluids under consideration are physiological saline, isotonic glucose solution, and horse serum. The matter is of importance in cholera where it is not always possible to give all patients in an epidemic the routine intravenous saline. I see that recent work has shown glucose given per rectum to be useless. I have seen it stated that a shipwrecked crew without water can be spared the pangs of thirst by the administration of sea water per rectum. Is there any experimental proof of this?

INCOME TAX

Allowance for Garaging Cars

"T. C." and his assistant make use of one car and three cycles. There is one garage at the surgery and another at "T. C.'s" private house. What should he deduct for the cost of garaging? Would a commercial rate of 7s. 6d. for the car and 2s. 6d. for each cycle be reasonable?

* * The amount of the deduction must be determined by the actual facts of the case, but the commercial rate basis may be

needful to check the amount arrived at—but it has to be remembered that those figures would presumably cover owner's profit and expenses of management which do not arise on the present facts of the case. The amount deducted is a reasonable proportion of the rate paid on the promise of which the garage forms a part and of the net Schedule A assessments also. These assessments will include the ground rent payable, which, therefore, cannot be reckoned as an additional expense. If the surgery garage is separately assessed, that will, of course, simplify the calculation. Repairs, and any other expenses specifically relating to the garage, will obviously need to be included.

Benefit of Free Board and Lodging

"T V D" asks for a reference to the leading case referred to in an income tax reply in our issue of July 14th.

* * The decision of the House of Lords in *Tennant v Smith* [1892] A.C. 150, is the authority for the proposition that an advantage not convertible into cash is not assessable as tax. The distinction between such a case and that where a salary is paid after a deduction for cost of lodging, etc., as provided by the agreement for service, was dealt with in the Divisional Court in the more recent case of *Cordy v Gordon*, [1925] 2 K.B. 276.

Change in Proprietorship—Cash Basis

"DORSET" explains that up to a date in June there were four partners in the practice, but one partner died and the practice has since been carried on by the remaining three. As a result if the present proprietors join with the executors of the deceased partner they may now require the income tax assessment for 1928-29 to be treated as if the practice had ceased and been recommenced. If they do so, can they discard the cash basis as regards the "new" practice?

* * We know of no reason why the cash basis should be continued and if it is dropped, and the legally correct method of gross bookings, less a specific deduction for bad debts, substituted, the revenue authorities cannot claim to bring in the old debts as chargeable to tax in the hands of the "new" firm. They could presumably claim that the past assessments should be revised to put them on the basis of bookings, on the ground that if the cash basis is abandoned the new basis should be applied to all the years now within the assessment time limit of six years. But if the practice has been fairly constant during that period, the result would not be very substantial. It should, perhaps, be pointed out that if 1927 was a "good" year the deceased partner's executors may be unwilling to join in the re-election as it would involve them in an increased payment of tax for 1927-28.

LETTERS, NOTES, ETC.

THE "MEDICAL DIRECTORY"

THE Editors of the *Medical Directory* inform us that their annual circular has been posted to each member of the medical profession. Should any form not have reached its destination, they will be glad to send a duplicate. They hope that completed forms may be sent to them at 40 Gloucester Place, Portman Square, London W1 by an early post.

MEDICAL TREATMENT IN CHINA.

FLEET SURGEON W. E. HOME (Kew) asks whether there is any truth in the oft-repeated story that the Chinese so long as they are well pay retainer fees to their doctors which are discontinued during illness. He adds that his Chinese informant—one, a Manchurian lady formerly on the staff of the old Empress—declares that they have never heard of the system. He suggests that some medical missionary might be able to supply first-hand evidence to settle the question.

MOHAMMEDAN PILGRIM SHIPS

DR. RISTEAD MAO EOIN (R. A. Tobson) writes from Trichinopoly South India. With regard to the letter of "Port Said" (May 26th, p. 930) I served as surgeon on a cargo boat in 1924 which carried about 1,000 pilgrims from Singapore to Jeddah. The pilgrims were housed for the most part in space which is ordinarily occupied by cargo, temporary latrines and cook houses were erected and rations of fresh water and firewood issued. All foodstuffs were carried by the pilgrims themselves. An adequate supply of medicines was provided by the company. The ship's officers were attentive and considerate. Deaths during the voyage were nil. The daily sick rate was about 10 per 1,000 of which about 3 per 1,000 were too ill to walk to the dispensary. I might mention that the company with which I served—the Blue Funnel Line—has the reputation of being the best English company in the pilgrim carrying trade. I agree with Dr. Pope (June 9th, p. 1007) that conditions of health on the return journey from Mecca are always much worse and that much of the sickness on the westward journey is due to many invalids and feeble old people undertaking the pilgrimage. They are not refused a passage for that reason unless their disease be infectious. One of my pilgrims walked aboard at Singapore

during an attack of acute lobar pneumonia. Only one pilgrim was rejected by me at the embarkation port—an infant suffering from ophthalmia neonatorum. I understand that pilgrim ships sailing from Dutch ports are subject to strict regulations as regards the housing and comfort of pilgrims. Mohammedans living under English rule are not, so far as I am aware, given any such protection. The only restriction I know of in their case is a rule forbidding the carrying of more than 1,000 pilgrims under the care of one surgeon.

INSULIN PATHIC SYNDROMES

IN the course of an address to the New York Academy of Medicine on the endocrine glands in relation to infancy and childhood Professor L. T. Barker of Baltimore after referring to the now well known syndrome of hypoglycaemia after a dose of insulin, has discussed the spontaneous hypoglycaemia, which is perhaps due to a pathological oversecretion of insulin. In adults carcinoma of the islets of Langerhans has been incriminated as causing "hypoparathyroidism and hypoglycaemia" (Wilder), and in Professor Bari's case a patient with frequent hypoglycaemic crises attributed after blood sugar estimations to overactivity of the islets was operated upon by Dr. Finney who removed the part of the pancreas where the islets were most numerous, the result was that the hypoglycaemic tendency was definitely diminished and the general condition much improved. This case is to be published in full by Drs. Sprunt and Trescher and is obviously of much interest as bearing not only on the possibility of a disease of the islets of Langerhans analogous to ophthalmic goitre, but on the way in which advances in treatment may stimulate by their untoward results, investigation into previously unrecognized forms of disease.

A BEGGING LETTER FRAUD

EVIDENCE of a systematic begging letter campaign directed against members of the medical profession was given at Cardiff in a case in which Jenn Marie Atherton, 22, was sentenced to twenty-one days' imprisonment for attempting to obtain 30s by false pretences from Dr. Sydney Blugham of Alfreton. It was stated that the accused sent Dr. Blugham a letter saying that her father was a former medical student of the same hospital and continuing: "He died a year ago of consumption and his allowance died with him. I am nearly desperate with worry as I have no relative to turn to." The letter then asked for 30s to enable the writer to travel to Llandudno where she had been offered a post. It was shown by the prosecution that the girl's father was alive and had lived with his daughter for some years. The police stated that they had had complaints from seventeen doctors who had received similar letters, and that the girl had previously been convicted for obtaining charitable contributions by fraud. In the *Journal* of August 13th 1927 (p. 290) we published details of a begging letter received by a London medical man from Cardiff and evidently from the same person appealing for help for the writer's family. The recipient in each case was told "you will probably remember him" (the father of the writer), but according to the earlier letter the father was not yet dead although seriously ill with consumption. As a rule, only a small minority of those who receive begging letters trouble to inform the police, even when they suspect the nature of the appeal. If seventeen complaints have been received at the Cardiff police station, it is probable that a much larger number of letters have been sent out and that others will follow in due course when Miss Atherton is at liberty.

ACCIDENTS WITH RAILWAY CARRIAGE WINDOWS

DR. B. W. RYAN (Bradford) writes: The holidays call attention to accidents peculiar to such times—one of these is that caused by a person thrusting his head through the centre pane of a railway carriage window under the impression that the window is lowered. Such accidents are most common in persons who are completing a long journey and sleeping in snatches. On awakening they find themselves in their exact situation and attempt to get out. Their accommodation has not time to adapt itself for the glass window. Added to this the uniformity of clear glass makes the surgery of accommodation and convergence peculiarly difficult. I suggest that all the centre panes of railway carriages should bear some prominent object embossed or engraved upon them about 6 in. below the upper crossbar which would not as an object of fixation and serve to stimulate the accommodation. Two of these accidents have been recorded in the past week.

ANGOSTURA BITTERS

Messrs. HENDERSON and Co. (LONDON) LTD., write with reference to a note on this subject in the *Journal* of June 2nd (p. 965). Angostura bitters do not contain and have never contained any angostura bark. The name "angostura" is derived from the fact that the bitters were originally manufactured as far back as 1824 in the town in Venezuela then called Angostura. The name of the town was changed by official decree in 1845 to Ciudad Bolívar, but the old name was still used for the bitters.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 33, 39, 40, 44, 45, and 46 of our advertisement columns and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 83.

Remarks

ON

HISTORICAL ASPECTS OF IDEAS
REGARDING DROPSY.

BY

JOHN D. COMRIE, M.A., M.D.,
F.R.C.P. Ed.

Physician to the Royal Infirmary, Edinburgh

The appearance of dropsy or hydrops, to give it the original Greek form of the name, is a symptom which cannot fail to attract attention, although it is probable that in a primitive state of society a person affected by a malady sufficiently severe to produce this symptom would not long survive. Dropsy is mentioned in the *Ebers papyrus* and on the clay tablets of medical prescriptions from ancient Assyria, with the treatment, material and magical, believed to be appropriate to the condition.

Hippocrates (400 B.C.) naturally has a good deal to say on dropsy, and he divides it into the three types of hydrops, *anasarca*, and *tympantes*. The first of these was a collection of fluid in the abdomen, by the second term he meant a collection of fluid dispersed generally through the flesh, while in the third there was an associated condition of flatulence.

In accordance with the general idea of disturbance in the humours as the cause of disease, he attributed dropsy, so far as he professed to theorize regarding the disease, to a malady of the spleen, in consequence of which the tissues liquefy and the belly and lower parts become full of water.¹ In other cases the formation of liquid was attributed to the liver, in others to the production of white phlegm, and in still others to dysentery.

Although this process of liquefaction of the tissues is regarded by Hippocrates as the essence of dropsy, he evidently distinguishes dropsies which, from their clinical aspect, are of different nature and of very different importance in their influence upon health and life. Dropsy in the legs, when it is combined with cough (by which apparently he means to indicate the filling up of the chest with fluid) he pronounces to be bad.² He recognizes that *anasarca*, beginning in the course of an acute illness with urine coming in small quantities and having little sediment, is of a bad type. The dropsy which is succeeded by epileptic attacks (and by this he evidently indicates *uraemia*) is also very serious. Dropsy accompanied by colic is bad, when it is associated with diarrhoea (and here he is perhaps thinking of tuberculous peritonitis with enteritis) it is fatal, while dropsy which yields to treatment for a time and then recurs is to be regarded by the physician as hopeless.³

In respect of treatment Hippocrates recommends that the flesh which has broken down and liquefied should be removed by laxatives, or the belly may be opened near the umbilicus and the fluid let out.⁴ As a purgative he recommends *veratrum in vinegar*.⁵

It is evident that the Father of Medicine does not profess to draw a clear distinction between different kinds and varying causes of dropsy, although he clearly indicates some of the conditions in which dropsy is a serious feature of illness.

At the Alexandrian School of Medicine Erasistratus attributed dropsies to sluggishness and hardness of the liver—what he called *scirrhus*, and we should designate *cirrhosis*.⁶

Galen, five centuries after Hippocrates, had a good deal more to say in detail in regard to dropsy, although he repeated most of what Hippocrates had pronounced. It is interesting to note that Galen, who wrote voluminously on the pulse, described the pulse of auricular fibrillation in *anasarca* as being small, rapid, irregular, and soft.⁷ Galen, however, failed to recognize weakness of the heart as the important causal factor in dropsy, in fact, he completely inverted the matter, and described the softness of the pulse and weakness of the heart as due to the softening of the heart and arteries caused by the dropsical fluid.⁸

He held that dropsies should first be treated by purgatives and at a later stage by the addition of remedies which drew off the humours from their place of formation, such as drugs which produced vomiting, provoked urine, etc. By blood letting also he declared that he had in some cases brought about cure of the dropsy. He was a great believer in various local applications which had the power of absorbing the fluid through the skin. Among these he mentioned with favour a paste, introduced by Asclepiades and consisting chiefly of cornflour, manna, and lard, which was smeared over the dropsical parts, also Egyptian earth and various forms of plasters. For the surgical cure he recommended that the abdomen should be punctured a little under the umbilicus towards the left with a knife shaped like a mrtle (leaf).⁹

As Galen had left the matter, so it virtually remained all through the Middle Ages, dropsy being regarded as a primary disease, like epilepsy or fever, of which the cause was practically undiscoverable. It continued to be regarded as in some way connected with disorder of the liver or the spleen, but there was no clear connexion between the two sets of phenomena. So matters remained right up to the seventeenth century.

I may be pardoned here, in this year of the tercentenary of Harvey's discovery, for making a short digression to the new idea regarding the functions of the body in health and disease which followed as a corollary to his principle of the circulation. Galen perfectly understood the function of the valves of the heart, and is at considerable trouble to describe them.¹⁰ He and his followers, however, imagined apparently a leisurely ebb and flow of humours, and had no conception of the whirling rush which proceeds constantly like a mill race through all the tissues of the body. When the vigour with which this process goes on is grasped it is easy to understand at the present day that any interference with it will naturally cause a stagnation of the fluid. The wonder is that nearly two centuries elapsed after Harvey's publication of the *De Motu Cordis* before the idea was generally accepted that failing power on the part of the heart was one of the main causes of dropsy. Malpighi and Leeuwenhoek, towards the end of the seventeenth century, demonstrated with their newly invented microscopes how the tissues were everywhere penetrated by minute vessels through which the blood corpuscles, floating in a fluid, passed in single file. Borelli and Pitcairne, about the same time, worked out with mathematical precision the hydrodynamics of this remote part of the circulation in a state of health, but there was as yet no attempt to apply the principle to the processes of disease.

A contemporary of Harvey, Theophilus Bonetus of Geneva, was the first person to issue a textbook of morbid anatomy. This, which was called the *Sepulchretum* and published in 1679, is a storehouse of all that was then known in regard to the anatomy of disease. He records numerous cases of dropsy, and mentions in one that the heart was of a great size, in another that a hardening was found in the heart, in a third that the right ventricle contained a pituitous substance like the yolk of egg, etc., but he does not anywhere connect these appearances with the cause of the dropsy.¹¹

A century later Morgagni's great work *On the Seats and Causes of Disease* carried the matter a little further. In regard to the cause of dropsy his pronouncement¹² was

"That by the force of hypotension, rather than by the authority of Hippocrates or the dissection of dropsical bodies most physicians were formerly induced to believe the liver first and after that the spleen to be the cause of dropsy you will learn from the *Sepulchretum* either in the place where it is shown that in the books of Hippocrates not any one or two viscera are supposed to be in fault but many or where many examinations of the viscera of dropsical bodies being produced, both of these viscera are demonstratively cleared from the charge. And certainly whatever part or whatever cause can for a considerable time retard the motion of the blood or lymph, or immediately increase the secretion of the moisture with which all the cavities of the body are furnished or in short prevent or diminish by any means its absorption may give origin to this disorder."

Morgagni is generally credited with having been the first person to describe disease of the mitral valve, and he cites numerous cases in which either this valve or the aortic valve was thickened, hardened, nodular, or even

¹ The opening paper in a discussion in the Section of History of Medicine at the Annual Meeting of the British Medical Association Cardiff 1928.

ossified. In several of his cases he demonstrates the co-existence of this and a collection of fluid in the pleural cavities,¹⁴ but he does not anywhere clearly specify the valvular defect as the mechanical cause of the dropsy.

Matthew Baillie appears to have been one of the first persons to be impressed by the important influence that must be exerted by a valvular defect of the heart on the general functions of the body. In notes on the illustrations in his atlas (1789), which show thickening and ossification of the heart valves, he remarks that it is obvious that such valves must perform their office very imperfectly.¹⁵

Meantime, the subject of dropsy was being approached from another point of view, that of clinical medicine and therapeutics, and it gradually became clear that, as regarded treatment, dropsy must be considered as a disease which in different cases is of diverse natures and due to varying causes.

In the year 1775 William Withering, M.D., physician to the General Hospital at Birmingham, was shown a family receipt for the cure of the dropsy which had been used for long by an old woman in Shropshire, and had sometimes made cures of this condition after the more regular practitioners had failed. The prescription contained some twenty herbs, but it was obvious that the active ingredient was foxglove. Withering accordingly, in the summer of 1776, obtained a quantity of dried foxglove leaves with which he commenced to experiment upon patients attending the dispensary at Birmingham, using first of all a decoction, then an infusion, and, later, occasionally the powdered leaves themselves. He used digitalis especially for a number of dropsical cases which presented themselves in 1779, following upon an epidemic of scarlet fever and sore throat, which had raged generally at Birmingham in the preceding year. As he had obtained good results with it, the use of the drug was communicated to the Medical Society at Edinburgh in February, 1779, and digitalis appeared in the new edition of the *Edinburgh Pharmacopoeia* in 1783 on the recommendation of Dr. Hope. Withering himself did not publish his results until 1785, by which time he had collected over 160 cases of dropsy, in some of which the use of digitalis had been attended with remarkable benefit, while others had shown no improvement whatever.¹⁶

The cases of dropsy in which he found digitalis effective as a cure were those in which the pulse was feeble or intermittent, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, and the anasarcaous limbs readily pitting under the pressure of the fingers. These were obviously cases in which the dropsy had followed mitral disease. There was, indeed, at the time when he wrote, no means available for making a correct diagnosis of this condition. He concluded that, though digitalis would not act universally as a diuretic, it did so more generally than any other medicine. He also observed that it had a "power over the motion of the heart, to a degree yet unobserved in any other medicine, and that this power may be converted to salutary ends." He did not, however, draw any closer connexion between the dropsy and the heart disease. He excluded from the beneficial action of digitalis ovarian dropsy and hydrocephalus or dropsy of the brain.

An important monograph upon dropsy of the ventricles of the brain appeared in the year 1768 from the pen of Robert Whytt, professor of medicine in the University of Edinburgh. This treatise was the first description of tuberculous meningitis, and gave an almost perfect clinical description of the condition as we now know it, although of course Whytt could not trace its cause to the tubercle bacillus. He showed that it was due to some compression of the absorbent veins, while the normal amount of secretion of fluid went on from the small arteries.¹⁷

Dropsy of renal origin was not recognized for another fifty years, but meantime fresh light was being thrown upon the development of dropsy by investigations into the function of the lymphatic vessels.

As early as 1622 Aselli, professor of anatomy at Pavia, had discovered the lacteals and their valves. By 1651 Pecquet had noted the existence of the receptacle of the chyle and its continuation as the thoracic duct, and in 1652 Jolive, an Englishman, in taking his doctor's degree

at Cambridge, presented in his thesis an account of the lymphatics, a matter which was more fully described in the *Nota Exercitatio Anatomica* of Olaf Rudbeck, professor of anatomy at Upsala, in 1652. Rudbeck described, under the name of *vasa serosa* or *aqueosa*, the vessels containing a clear watery liquid, which we now call lymphatics. A whole century passed, however, before people began to inquire seriously into the functions of these minute vessels. Priority in elucidating the nature of these vessels was claimed both by William Hunter and by Alexander Monro (secundus) of Edinburgh, and formed one of the celebrated medical controversies of the eighteenth century. Up to 1755 everyone supposed that the lymphatic vessels were simply a class of very minute veins which originated, like the red veins, from the arteries. Monro and Hunter suggested that the lymphatics were the absorbents of the body, and Monro, in 1757, published a thesis, *De Venis Lymphaticis Icturiosis*, in which he dealt with their origin from spaces in the connective tissues, a subject which he traced by a method of injection. Hewson, in 1774, published his celebrated *Description of the Lymphatic System in the Human Subject and in Other Animals*. After this time the absorption of fluid from the tissues by the lymphatics was fully established. This matter of scientific knowledge practically coincided with Withering's experiments on the use of digitalis in removing dropsy and with Morgagni's statement that dropsy was due to any cause that retarded the lymph or prevented the absorption of moisture from the cavities of the body.

The next step in clearing up the question of dropsy was the recognition of a cardiac type of this disease. Morgagni and other observers had already, about the middle of the eighteenth century, recorded numerous cases of dropsy in which, as an incident, abnormality of various heart valves or of the structure and size of the heart had been found, but they had not traced a connexion between the two sets of phenomena. The earliest case that I have been able to find in which suggestion is made of a definite causal connexion is recorded by Dr. Donald Monro, and is worth while quoting. He says:

"In the year 1750 I dissected the body of a man who died of an universal dropsy, in the presence of Dr. John Rutherford, professor of medicine in the university of Edinburgh. We could find no other cause of the disease than the ossification of the *valvula mitralis* in the left ventricle of the heart by which the orifice of that ventricle was so straitened, that I could scarce force my little finger into it. The heart itself was very large. While the man was alive, all the soft parts of the neck were raised by every systole of the heart in such a manner that the veins there seemed to have a pulsation."¹⁸

Monro, however, did not press this point of narrowing at the initial valve as being a common cause of obstruction to the circulation and consequently of dropsy. No doubt other cases were from time to time recorded in medical literature, but the first standard publication in which cardiac dropsy was definitely recognized seems to have been Corvisart's *Essai sur les maladies et les lésions organiques du cœur et des gros vaisseaux*, first published in 1806. He refers to the opinions of Bichat and others, so that the idea of cardiac dropsy may be said to have taken root with the beginning of the nineteenth century. Corvisart describes the case of a blacksmith, aged 20 years, who complained of dysentery and hæmorrhage from the bowels, accompanied by palpitation of the heart and general oedema of the body. From the strong, quick, and irregular intermissions of the pulse, Corvisart diagnosed at one of his clinical conferences "an organic lesion of the heart." The patient having died twenty-five days after admission to hospital, the *post-mortem* examination revealed dilatation of the left auricle and contraction of its opening into the left ventricle to "a kind of osseous slit through which a thin coin could scarcely have passed."¹⁹ Corvisart therefore contended that the dropsy, hæmorrhage, and other symptoms had all been due to the narrowing of the mitral valve and not to dysentery, to which, on the old view, the whole of the symptoms had originally been attributed. Since Corvisart's book had a wide circulation and great reputation, this may be regarded as definitely establishing cardiac disease in the position of a cause of dropsy instead of the dysentery, disease of the liver and spleen, etc., which had previously been considered the essential origin

It is important to note in passing that the method of diagnosing in percussion collections of fluid in the abdomen and in the pleural cavities had been first invented by Auenbrugger and announced in his *Inventum Novum*, published at Vienna in 1763. This practically coincided with the publication of Morgagni's great treatise. It was, however, for long completely disregarded, and became generally known only after a French translation had been published by Corvisart in 1808. Thus we may conclude that in most cases with only a moderate amount of ascites or hydrothorax the presence of the dropsy was missed during life until the beginning of the nineteenth century, when diagnostic methods became more precise.

A few years later we find the whole subject of the diagnosis of small collections of fluid in the pleural cavities and abdomen and the recognition of cardiac valvular disease during life placed on a firm basis by Laennec. This writer, in his *De l'Auscultation Mediate*, describes how, in the year 1816, he discovered by chance that he could hear the heart sounds more clearly through a rolled-up exercise book than when he applied his ear directly to the chest. This was the beginning of the stethoscope. Moreover, Laennec's careful observations on the sounds made by the normal and diseased heart, compared with the observations which he made on the same patients after death, laid a sure foundation for the diagnosis of organic heart diseases and their complications.¹ He described clearly, for example, a bruit "analogue à celui d'un soufflet" which corresponded to the contraction of the left auricle in a case that presented dropsy of the hands and legs, hydrothorax and ascites, and in which the cause was found after death to be a state of warty vegetations on the mitral valve with rupture of one of its tendons and dilatation of the two ventricles. He gave also vivid pictures of other cases in which cartilaginous changes and narrowing of this valve had been the cause of dropsy.² Laennec's work may be regarded as the statement of our present-day knowledge regarding cardiac valvular disease as the mechanical cause of one form of dropsy.

A new chapter in the history of dropsy was gradually opening while the elucidation of cardiac dropsy was still obscure. William Charles Wells seems to have been one of the first to call attention to another type of dropsical cases in a paper "On the presence of the red matter and serum of blood in the urine of dropsy which has not originated from scarlet fever." The fact that dropsy accompanied scarlet fever and other acute disease, and often led to the patient's death had, of course, long been recognized. Wells, in 1811, drew attention to the fact that dropsy sometimes came on gradually, with a scanty secretion of urine, sickness, and other disorders of the digestion, bad smelling breath, and convulsions. For years after these patients recovered, the urine, although clear, was found to contain blood serum because "being boiled it became turbid, and afterwards deposited a considerable quantity of curdy matter." "Nitrous acid" was also used as a test by Wells. Wells mentioned twenty-nine cases of dropsy of the skin not preceded by any disease to which dropsy was generally attributed, among which the urine of twenty-three gave this test. As, however, he did not bring any of the cases to post mortem examination, the cause of the dropsy still remained in doubt.³

The subject was pursued further very shortly afterwards by John Blackall, physician to the Devon and Exeter Hospital, who published a manual upon *The Nature and Cure of Dropsies*. Blackall divides dropsy primarily into that form in which the urine is coagulable by heat and that in which it is not coagulable. Despite the work of Corvisart, however, he does not recognize the mechanical effect of cardiac disease as an essentially important cause. He refers to observations by previous persons, such as Cotunnus, who had described a "mucilaginous diabetes connected with the beginning of some dropsies," Latham, who in 1795 had described "diabetes with a copious discharge of serum from the kidneys," and others. Blackall's work deals largely with the matter of treatment and the clinical indications for the use of different remedies, such as squills, oil of turpentine, cantharides, copper sulphate, potassium citrate, tobacco, digitalis,

infusion of broom tops, tincture of opium, tapping, and scarification.

It is not till we come to the classic work of Richard Bright, of which the centenary was celebrated last year, that a precise account is presented to us of disease in the kidneys as a cause of one type of dropsy.⁴ Bright made a careful and complete study, both clinical and pathological, of his cases, and published admirable plates showing the actual changes in the kidneys of the dropsical patients. Laennec had published in 1826 the second edition of his great work, and the connexion of heart disease with dropsy was firmly established. Bright had made a three years' study of dropsy in the wards at Guy's Hospital, and he says:

"Where anasarca has come from exposure to cold or from some accidental excess, I have in general found the urine to be coagulable by heat. During some part of the progress of these cases of anasarca, I have in almost all instances found a great tendency to throw off the red particles of the blood by the kidneys, betrayed by various degrees of hæmaturia, from the simple dingy colour of the urine which is usually recognized or the slight brown deposit,—to the completely bloody urine when the whole appears to be little but blood and when not unfrequently a thickropy deposit is found in the bottom of the vessel."

He describes other chronic cases as follows:

In persons long the subjects of anasarca recurring again and again worn out and cachectic in their whole frame and appearance and usually persons addicted to an irregular life and to the use of spirituous liquors. In all the cases in which I have observed the albuminous urine it has appeared to me that the kidney has itself acted a more important part and has been more deranged both functionally and organically than has generally been imagined. In the latter class of cases I have always found the kidney disorganized. In the former when very recent I have found the kidneys gorged with blood. And in mixed cases where the attack was recent although apparently the foundation has been laid for it in a course of intemperance I have found the kidney likewise disorganized.

The matter was subsequently verified in 1829 by Christison, who reported several instances of albuminuria with renal disease and who mentioned the progressive diminution of the urea in the urine and the increase of the urea in the blood.⁵ Bright recurs to the subject in the second volume of reports of medical cases, published in 1831, where he deals with dropsy as it affects the brain both in cases of kidney disease and those due to various local causes. The importance of kidney disease as a cause of epileptiform convulsions, paralysis, and other signs of dropsy interfering with the nervous system was fully described by Bright, and has, perhaps, come to receive too little attention in recent times.⁶

Still another chapter, clearing up what had been regarded by earlier physicians as a puzzling group of dropsical cases, commenced with the description by Sir William Gull in 1873 of two cases showing a cretinoid state supervening in adult life in women. He gave a clear clinical picture of two elderly women who had come under his observation because of increasing languor and the development of a gradual appearance of dropsy. He described the complexion as having been

entirely different to what one sees in the bloated face of renal anasarca. This suspicion of renal disease failing anyone who should see the case for the first time might suppose that the heart was the faulty organ and that this general change in the features and increase of bulk were owing to venous congestion. But neither would this be confirmed by an exact enquiry into the cardiac condition.

He had at that time no explanation to give of the cause that led to this state. With regard to treatment all he could say was

The best suggestions I can make are to let events take their course very much maintaining the strength by ample regimen and fresh air and by the occasional or more or less continuous use of such remedies as quicken the peripheral venous circulation. Hot air bath or warm bath, frictions etc. but the general good effect will I think be limited.

Four years later William M. Ord, physician at St. Thomas's Hospital, went further and described in detail five cases of this condition which he carried to autopsy and showed to be associated with atrophy of the thyroid gland. He found that the skin, when cut up into small fragments retained its oedematous condition, whereas the skin of dropsical patients collapsed when treated in this way, and he further found that fifty times the normal quantity of

mucin could be extracted from the subcutaneous tissues of these persons. He therefore gave the name of "myxoedema" to supposedly dropsical cases of this type.²² The separation of these cases, which formerly had been classed as a type of dropsy, was further made in 1823 by Kocher, who found that the condition developed after removal of the thyroid gland,²³ and by Semon,²⁴ who in the same year suggested the identity of cretinism, myxoedema, and cachexia strumipriva, and whose suggestions on identity of origin were confirmed through an investigation held by the Clinical Society of London in the following year.²⁵

In contrast to the helplessness expressed by Gull in 1873 for the betterment of these cases, Murray²² in 1891 used with good result hypodermic injections of glycerin extract of sheep's glands, and, in 1892, the treatment was further improved and simplified by Hector Mackenzie and Fox,²² who independently and successfully used the administration of sheep's thyroid gland, or its extract, by the mouth in the treatment of myxoedema.

Other forms of dropsy of a localized nature have from time to time been shown to be due to conditions which offer a local obstruction to the circulation of blood or lymph. It is unnecessary to particularize these, but one may simply mention the discovery by Bancroft in 1876 of the filaria which causes elephantiasis and allied conditions that were for long a puzzle to physicians practising in tropical regions.

SUMMARY

Dropsy from the earliest times was an obvious morbid condition, and was for long regarded as a disease *suu generis*, due to liquefaction of the tissues. The ancient Greek physicians attributed it chiefly to a disorder of the liver, and hardening of this organ was regarded as the principal cause by the Alexandrian School of Medicine. Galen regarded the defective action of the heart, which is often an accompaniment of dropsy, as an effect rather than a cause. In the eighteenth century Morgagni drew attention to the frequency with which the heart is found to show valvular defects and other disorders in cases of dropsy, but he did not carry the matter further. Withering, who introduced the use of digitalis in 1775, recognized that only certain cases of dropsy were amenable to treatment by this drug. He described as the type of case in which the dropsy was chiefly benefited persons showing symptoms which we can now recognize as being those of advanced cardiac disease, although the means of diagnosing valvular disorder was not at the time available to him. In the beginning of the nineteenth century Corvisart followed by Laennec, placed the diagnosis of cardiac disease on a sure foundation and showed that dropsy was frequently simply a sequel of this type of disease. The recognition of kidney disease as a cause of dropsy was first made early in the nineteenth century when Wells, Blackall, and others pointed out the fact that the presence of albumin in the urine was a prominent feature in certain dropsical cases, and these observations were placed on a sure footing by Bright in 1827. A further group of cases in which neither the heart nor the kidney is found to be at fault was demonstrated by Gull and Old, in the seventies of last century, to be due to atrophy of the thyroid gland and to be of a different nature from simple watery oedema.

DISEASES OF THE CORONARY ARTERIES*

BY

GEO. A. ALLAN, M.D., F.R.F.P.S., M.R.C.P.,
Visiting Physician, Western Infirmary, Glasgow

THE maintenance of an efficient circulation to the heart muscle is of fundamental importance if the heart is to be able to perform its function in health or disease to the best advantage. One of the essential requirements for this purpose is the possession of healthy coronary arteries, and it is to a consideration of diseases of these vessels that I have been asked to direct your attention.

Before embarking on the subject proper it might not be inappropriate to indicate the scope of the discussion in relation to the title. Although diseases that affect the coronary arteries are the same as those that affect arteries in general, discussion of minute points in classification or of pathological details would be unfortunate and probably profitless. One should concentrate rather on the effects produced on the heart by such diseases as receive general acceptance. Again, because of the widely recognized connexion between angina pectoris and these diseases, one must guard against any concentration on the theories of angina pectoris, interesting though that might be in itself, as a detraction from the value of the main subject before us.

Further, coronary artery thrombosis is an important manifestation which has attracted much attention in recent years and will no doubt be freely discussed to-day, but it would denote a narrow outlook if discussion became limited to this condition. There is a danger in any of these directions of overlooking other important considerations.

In so far as special aspects of the subject will be dealt with in detail by subsequent speakers, these opening remarks will best serve their purpose if I survey in a general way some of the essential features of the problem.

HISTOLOGICAL

Disease of the coronary arteries has been recognized for a considerable time, and its association with angina pectoris as more than a coincidence has been widely accepted, though many have refused to accept the view that coronary disease offers a complete explanation of that condition. Prominent among the latter have been Allbutt,¹ Mackenzie,² Cabot,³ and Vaquez.⁴ In recent years, fifteen to twenty at most, prominence has been given to certain symptoms, anginal in nature, which have been found to be associated with coronary blockage—usually by thrombosis *in situ*. The importance of this syndrome, to which further reference will be made, is undoubted, and has now directed attention to these vessels. Inquiries into the literature have been made by Hamman,⁵ and more recently by Parkinson and Bedford,⁶ and while it would appear that the association of special symptoms with occlusion of the coronary blood supply had been recognized as far back as 1878, it is only during the last few years that it has received intensive study and that a clear distinction has been established between it and the more widely recognized syndrome of typical angina pectoris.

In this country the papers published in 1925 by McNee⁷ and by Gibson⁸ have helped to focus attention on this subject. It is interesting to note, however, that in 1887

*A paper read in opening a discussion in the Section of Medicine of the Annual Meeting of the British Medical Association Cardiff 1928.

Landsay¹² of Glasgow, whom I had the privilege of assisting in his clinic for a few years, in a lengthy paper on "Fibroid degeneration and allied lesions of the heart and their association with disease of the coronary arteries," made a careful analysis of the literature. One of the earliest cases he noted was recorded by Sir William Gairdner in 1854—¹³ a case of ossification of the coronary arteries with tendinous degeneration of the heart. Steven¹⁴ recorded sixteen cases with clinical histories and post-mortem reports, emphasized the relationship existing between disease or obstruction of the coronary arteries and fibroid degeneration, and distinguished in this connection between this fibrous transformation and chronic interstitial myocarditis due to other causes. It may be mentioned at this point, though somewhat anticipating subsequent remarks, that in two of the cases recorded Professor Coats demonstrated, by injection with Prussian blue, free anastomoses between a perian coronary artery and the branches of a blocked vessel, and also between branches supplying the two auricles and the two ventricles.

Coincidental with this increased attention to the clinical aspects very important anatomical investigations have been made, and to Gross¹⁵ and his collaborators physicians owe a debt of gratitude. It may be appropriate at this point to mention some of the results of their work. The blood supply to the heart is subject to much variation, but certain main facts ought to be borne in mind.

The right coronary artery emerges between the pulmonary artery and aorta, passes to the right in the auriculo-ventricular groove as the right circumflex branch, and, crossing the acute margin, continues to the posterior aspect of the heart, where it gives off the posterior descending branch in the inter-ventricular groove. It supplies the entire right ventricle except the left third of the anterior wall. It also supplies the right half of the posterior wall of the left ventricle and a strip of the inter-ventricular septum.

The left coronary artery divides, almost immediately after its origin from the left anterior sulcus of the aorta, and under cover of the left auricle, into two branches, the chief branch being the anterior descending branch which passes down in the anterior inter-ventricular groove to the apex, curves round the apex, and ascends the posterior wall. The other, the left circumflex branch, passes to the left in the auriculo-ventricular groove. The left coronary artery supplies the left ventricle except the right half of the posterior wall, the left third of the anterior portion of the right ventricle, and part of the septum. Thus both vessels supply part of the posterior wall of the left ventricle, the anterior wall of the right ventricle, and the septum. The left aspect of the left ventricle and the anterior papillary muscle of the ventricle are only supplied by the left coronary artery. Further, the right branch of the auriculo-ventricular bundle is only supplied by the left coronary artery, while the left branch is usually supplied by both.

From his studies Gross also concludes that the heart is perhaps the richest organ in the body as regards capillary and pre-capillary anastomoses between branches of the same artery as well as between branches of both arteries, and, further, that as age advances there is also an anastomosis between the vessels in the epicardial fat and other adjacent parts and the coronaries—a fact which has a certain clinical bearing in explaining some of the features presented by cases of occlusion in later life.

Recently Kugel,¹⁶ a co-worker with Gross, has more fully demonstrated that an artery, called by him the "arteria anastomotica auricularis magna," which constantly links the right and left coronary arteries, usually passes from the circumflex branch of the left coronary artery to the circumflex branch of the right coronary artery through the inter-auricular septum. Incidentally this is the artery which sends twigs to the aortic cusp of the mitral valve when that valve is vascularized.

The question of anastomosis has been investigated much earlier and from different standpoints. In more immediate connexion with our discussion one might mention the work of Millar and Matthews¹⁷ on ligation of the descending branch of the left coronary artery in dogs from which the presence of anastomosis was inferred, and the more recent

and more extensive work of Smith,¹⁸ who arrived at the same conclusion by a similar method. Smith further correlated certain electro-cardiographic results with ligation of the left descending branch in dogs, and among several clinical cases reports,¹⁹ with electro-cardiographic records, one of a man who had the left descending branch ligatured for the stoppage of hæmorrhage from the heart wall following a self-inflicted wound.

MONOD ANATOMY

When we come to consider the morbid processes which are prone to affect the coronary arteries, we find that these can be classified into four clearly defined conditions. A classification built on minute histological detail is not necessary for the purpose of this discussion, and would probably in any case lead to pointless argument, but unless some uniform and simple classification is accepted confusion is likely to arise owing to the variety of terms that are often applied to the same pathological condition.

The four conditions with which I shall deal are atheroma, arterio-sclerosis, syphilis, and calcareous degeneration. As an example of the need for uniform nomenclature may be cited the cases of three recent papers directly or indirectly dealing with coronary artery disease. Apart from syphilis, in one English paper atheroma is the only term employed to denote lesions of the coronary arteries, while in another English paper the term arterio-sclerosis alone is employed. In an American paper the term arterio-sclerosis is used with hypertension as an added condition, while the term atheroma is not once mentioned. The term athero-sclerosis also occasionally crops up. A definition of the terms proposed to be employed would therefore appear to be necessary.

Atheroma—The commonest primary lesion in the coronaries is a patchy disease, first affecting the deeper layers of the intima. While there may be proliferation of fibrous elements on the aspect nearer the lumen of the vessel the deeper parts tend to degenerate, and in the later stages deformity is produced, encroaching on the lumen. Whether beginning originally as a fatty degeneration or not it is essentially the same condition as that called atheroma in the aorta, and, though with less frequency in the coronaries than in the aorta, is liable to produce atheromatous ulcer with a special tendency to thrombus formation. Atheroma is the term which I shall employ for this condition, as it affects the coronaries. It is to be noted that not only is the disease patchy in its local manifestation, but that it is also quite irregular in its incidence in different parts of the same body, so that the aorta, the coronaries, or the cerebral arteries may be the seat of well-marked atheroma though the accessible arteries of the body give no indication of its presence.

Arterio-sclerosis—The second lesion met with is a much more diffuse process, characterized by thickening of the media and intima, probably beginning in the media as a hyperplasia and leading at times to a certain degree of fibrous transformation of the muscular wall. It is the same as that described as the arterio-sclerosis of high blood pressure, and it may or may not produce any narrowing of the lumen of the vessel. It is much more uniform in its distribution throughout the body than is atheroma, and may be found throughout the vascular system, though certain parts may suffer more than others. The term arterio-sclerosis shall be confined to this type.

Syphilis—While aortic syphilis is one of the commonest visceral manifestations of that disease its presence in the course of the coronary arteries is comparatively rare. The coronary arteries, however, are liable to be implicated at their orifices in a patch of syphilitic mesoarteritis, thus producing narrowing of their lumina where they arise just above the aortic cusps.

Calcification—The fourth condition met with is calcareous degeneration, and it is frequently found superimposed on either atheroma or arterio-sclerosis, though it may occur as a primary medial degeneration. The deformity it produces in the coronary arteries in association with atheroma makes it a potent factor in diminishing the lumen, either directly or by the formation of thrombus on its surface.

If the purists in pathological terminology will agree to

accept such a classification it will, I am sure, meet all the requirements of the present discussion.

To obtain some idea of the relative frequency of these lesions of the coronary arteries, through the courtesy of Professor Muir, I took the figures from 1,000 consecutive *post-mortem* examinations made in the Western Infirmary, Glasgow, using only the routine reports of the naked eye findings. It will be understood, therefore, that the figures will be below, rather than above, the actual, because the state of the coronary arteries was not mentioned in every report, and, further, the coronary arterioles did not come under observation.

Under these conditions I was surprised to find that out of 1,000 consecutive *post-mortem* examinations made, there were 371 cases in which note was made by naked-eye observation of a lesion, whether trifling or severe, of the coronary arteries (see table). Of this number the average

*Lesions of Coronary Arteries with Accompanying Muscle Defects,
Found in 1 000 Consecutive Post-mortem Examinations*

Coronary Lesions	Number	Fibrosis Patchy or Diffuse	Fibrosis and Fatty	Fatty Only	No Fibrosis or Fatty
A	162	63	7	26	66
A and A S	96	52	1	12	31
A and C	26	18	3	1	4
A and S	8	2	0	0	6
A A S and C	6	6	0	0	0
A A S and S	1	1	0	0	0
A S	60	30	1	8	21
A S and C	4	1	0	1	2
A S and S	1	0	0	0	1
C	4	3	0	0	1
S	3	2	0	0	1
Total lesions found	371	178	12	48	133
No lesion	629	68	—	—	—

A = Atheroma A S = Arterio-sclerosis C = Calcification S = Syphilis

age of the patients was 55.4, the youngest being 13 and the oldest 85 years, and the causes of death were about as varied as one gets in any general hospital. Of these 371 cases 238 showed a definite lesion of the myocardium, 178 presented fibrosis, either patchy or diffuse, 12 fibrosis with fatty change, 48 fatty change alone, and in 133, or 35.9 per cent, no obvious change was present or there was only simple or brown atrophy or hypertrophy. Thus the predominant lesion present was fibrosis, as it was found 180 times (51.2 per cent) in 371 cases with coronary artery lesions. In the remainder of the 1,000 cases in which no lesion of the coronary arteries was noted fibrosis occurred in only 68 (10.8 per cent), the average age being 48.4 years. The lesions found in these 371 cases, with the percentage incidence of fibrosis were as follows:

Atheroma	299 (80.6%)	with fibrosis in	153 (51.2%)
Arterio-sclerosis	168 (45.3%)	"	92 (54.7%)
Calcification	40 (10.8%)	"	31 (77.5%)
Syphilis (at or near an orifice)	13 (3.5%)	"	5 (38.0%)

Using fibrosis, then, as an index of the effect of the various lesions of the coronary arteries, we found that calcification when present was the factor most likely to produce a lesion of the myocardium. It was usually found in association with atheroma or with atheroma and arterio-sclerosis.

There were 97 cases in which the lesion of the arteries was specially noted as producing definite narrowing or actual blockage of the lumen.

Atheroma was present	in 85	with fibrosis in	82 per cent
Arterio-sclerosis	in 31	"	84
Calcification	in 33	"	85
Syphilis	in 7	"	57

Fibrosis was present in 78, or 80.5 per cent of the 97 cases in contrast with 51.2 per cent of the whole group.

Thus, it may be inferred that when a lesion is sufficiently severe to narrow the lumen, no matter what the lesion, fibrosis is the natural result.

The last group I extracted from this series was that of 58 cases in which the patients died suddenly from coronary artery disease, or in which there was definite occlusion of a coronary artery or main branch. The average age in this group was likewise 55 years. Of the 58, atheroma was present in 49, or 84 per cent, arterio-sclerosis in 13, or 22 per cent, calcification in 20, or 34 per cent, and syphilis in 11, or 19 per cent. It is important to note that while this group is a little less than one-sixth of the total, about one-sixth of the cases of atheroma are found in it, one half of the cases of calcification, three-fourths of the cases of syphilis, but only one twelfth of the cases of arterio-sclerosis. This supports the view that atheroma, the commonest lesion, is also a serious one, while calcification or syphilis materially increases the gravity of the case in the direction of promoting occlusion of the vessel. Fibrosis was present in 48 of these cases, but there were 10 in which there is no note of any fibrosis in the heart muscle.

These cases present striking instances of the adaptability of the anastomotic channels in suitable circumstances, one of the conditions being slowness of the constricting process. The average age of the 10 patients was only 41. Space alone forbids details of these patients, all of whom died suddenly, all had well-marked, often extreme, old coronary lesions, and yet presented no gross fibrosis. More than half the cases had syphilis. One case must serve as an example. A female, aged 40, had suffered from angina for five years. At autopsy the right coronary artery was completely occluded with arterio-sclerosis, and there were syphilitic lesions in the aorta. The left coronary artery was small. There was no gross fibrosis and no recent thrombosis.

From this study, in addition to the general information regarding the frequency of the lesions and their effects, three points emerged which are worthy of note: (1) severe coronary artery narrowing may be present without obvious lesion in the myocardium, (2) old standing severe arterial lesions and actual occlusion with fibrosis may be present with no clinical history of its occurrence, (3) patients may die with symptoms suggesting coronary artery occlusion in which no such lesion is found.

GENERAL EFFECTS OF CORONARY ARTERY DISEASE

In general it may be said that there is a tendency for disease affecting the coronary arteries to produce diminution of their lumen. Rupture of a coronary artery, a condition analogous to that producing cerebral haemorrhage, must be very rare. Undoubted embolism causing blockage was not noted in this series.

The effect of the narrowing is to produce starvation atrophy in the parts supplied, followed by replacement fibrosis, or, if sudden complete occlusion is produced, infarction results, which may show necrosis and at a later date fibrosis, or sudden death may occur before either is manifest. The infarction is usually smaller than the area supplied by the blocked artery and is generally found to affect the middle or inner two-thirds of the heart wall. Fibrosis may, if sufficiently general, lead to dilatation of the chamber affected, or, if more localized and sufficiently severe, to aneurysm of the heart wall. As the descending branch of the left coronary artery is the vessel most commonly involved, the fibrosis is usually most marked towards the apex of the left ventricle, in the anterior papillary muscle of the left ventricle, and in part of the inter-ventricular septum.

If one takes a sufficiently wide outlook of the subject, it will be apparent that there can be no diagnostic symptomatology which will cover all cases of coronary artery disease. Thus it may be remembered that in the series of cases to which I have alluded the disease did not progress so far as to interfere appreciably with the blood supply in 133, or 35 per cent of the cases, at least no gross lesion in the muscle was apparent. In the remaining 238 cases only 58 could be said to have died as an immediate result of coronary artery lesions. In some of these a preliminary diagnosis, which would have been of value as

a guide to treatment, could not have been made, as the terminal event was the first indication of ill health. In an unknown proportion of the remainder, the coronary artery narrowing was no doubt a factor which promoted a fatal termination in the disease from which the patient chanced to die. In some patients death was due to ordinary cardiac failure, with or without dropsy, without any special symptoms or signs which might distinguish them from those dying with myocardial degeneration from other causes. In cases of arterio-sclerosis with high blood pressure, or in cases with evidence of atheroma in peripheral vessels, one might surmise that fibrosis of the myocardium due to these lesions in the coronary arteries was the cause of disease, if no other obvious cause was present. In some of them no doubt a more careful inquiry into the history during life might have directed the attention to the coronary arteries and made a diagnosis possible in view of the symptoms and signs that we now know occur in typical cases.

CORONARY ARTERY OCCLUSION

When the blockage is abrupt, as from thrombosis on an atheromatous or calcified patch, certain features are present with such regularity as to make diagnosis reasonably sure. Even when coronary artery thrombosis is recognized it must be understood that the result is still variable, depending on the size of the artery blocked, the actual branch that is affected, and the age of the patient. Hamman,⁵ in his review on the subject, has divided cases of coronary artery thrombosis into six classes, according to the course of events—namely (1) Cases of sudden death (2) Death in a few hours or days (3) Continued myocardial insufficiency, with death in weeks or months (4) Recovery after grave symptoms (5) Cases that are not grave but recognizable (6) Mild or uncertain cases.

The clinical features and diagnosis of coronary artery thrombosis will be dealt with in detail by subsequent speakers. The features that demand attention in coming to a diagnosis, and which I trust will be fully discussed, are, among others, the duration and situation of the pain, the associated symptoms such as collapse, vomiting, respiratory and mental distress, such signs as the rate and rhythm of the heart, the fall of blood pressure, pericardial friction, fever and leucocytosis, and the information that may be derived from electro-cardiograms.

I forbear to say more on these points than to repeat what emerged from the pathological inquiry. In a few cases old organized thrombosis may be present at autopsy without a history of antecedent acute illness, or there may be what appears to be a typical history and no thrombosis is found. The diagnosis must therefore be carefully assessed or it may readily overstep the truth.

PROGNOSIS

Once the diagnosis has been made the outlook is uncertain, and even the immediate prognosis can only be assessed after time has elapsed to gauge the response to treatment. In almost all cases the ultimate prognosis is bad, particularly in view of the absence of any evidence that arterio-sclerosis, atheroma, or calcification can be influenced materially by any known line of treatment. Gradually increasing cardiac weakness and sudden death at a subsequent date are not uncommon features. Until the diagnosis of minor manifestations is more accurate the number who recover cannot be stated. Judging from the old lesions found at autopsy those who make a good recovery, at least temporarily, must be fairly numerous.

TREATMENT

In considering treatment one must clearly distinguish between treatment of the actual disease which is affecting the coronary artery and treatment of a complication that may arise in the course of that disease, such as thrombosis.

It may be advisable to speak first of treatment of a case of coronary artery thrombosis. When the patient is struck down with such a catastrophe the first indication is to relieve the pain. The pain presents a striking contrast, in respect of its response to treatment, to that of true angina pectoris, where vaso-dilators may give instant relief. In this condition morphine is required, and often in large

doses. It may be stated that in cases of persistent anginal pain, or of low blood pressure, amyl nitrite is seldom effective and is usually dangerous. Morphine also aids in giving to the patient the mental and physical rest that is so essential. Some find digitalis of great value when the heart rate is accelerated, and in cases with auricular fibrillation the indication is obvious. Cases that rally from the initial attack, but present in time the ordinary signs of cardiac failure, should be treated along the usual lines for that condition.

I have for some time been impressed with the value of glucose in strengthening the heart in cases of myocardial weakness, but I have not been able to follow a sufficiently large series of cases to make any dogmatic statement. The dose I have employed has been half a pound daily, and I should like to have the views of others who have adopted this line.

In considering treatment of the actual disease of the coronary arteries one must admit that the ideal stage at which to deal with it is the stage before it has produced any effects on the heart, and the treatment resolves itself ultimately into the prevention of such conditions as atheroma and arterio-sclerosis. This implies a knowledge of etiology that is far from efficient.

Arterio-sclerosis of the hypertensive type has been much discussed for many years. As we have seen, it is a widespread condition as a rule, and so may be recognized before it has produced any effect on the cardiac muscle. Since the introduction of the sphygmomanometer some useful and much useless speculation has been printed. In certain cases it would appear that the thickening of the arterial wall is a direct result of hyperpiesis without kidney disease, while in others disease of the kidney appears to produce both. Over twenty years ago W. Russell¹¹ enunciated the view that arterio-sclerosis was due to the putrefaction of protein bodies in the intestine, and a few years ago Batty Shaw,¹ in his work on hyperpiesis, gave further support to that view. Treatment directed against the causes of hyperpiesis may then be of some value. The association of arterio-sclerosis and hard physical labour has not been clearly defined, though all conditions that tend to raise the blood pressure, even intermittently, over a long time may be expected to play a part.

Atheroma is more elusive even than arterio-sclerosis, there need be nothing in the patient to give a clue to the condition. Irregular in its distribution as it usually is, and not infrequently confined to inaccessible vessels, no history of its presence may be forthcoming till an accident, such as cerebral or coronary thrombosis, occurs. Its predilection for the aorta should direct attention to a careful assessment of all points that might assist in a diagnosis. It causes a weakening of the elastic tissue and leads to fusiform dilatation, which may be detected by x-rays, by percussion over the manubrium, by palpation in the episternal notch, or by accentuation of the aortic second sound, these being of most value when the blood pressure is low and the Wassermann reaction negative.

With regard to the causes, one title—that of senile atheroma—suggests that it is a natural process associated with old age. Though resident physicians have been known to index cases as senility and enter them on dismissal as cured, the prospect is not so hopeful for those who have had a little more experience in their profession. It is scarcely possible to assign any cause for the condition in the present state of knowledge. It is essentially a degenerative process. Age, physical strain, infections, and disorders of metabolism have all been assigned as causes in different cases. The special susceptibility of the coronary arteries has suggested that one of the factors may be the constant buffeting they receive from the contracting ventricles, and it has been suggested that the relative predisposition of the descending branch of the left coronary artery might be explained by the position of the vessel in relation to the sternum.

In these remarks I am afraid I have only presented what are to me the difficulties and have not added anything constructive to the treatment of these diseases. It is important, however, to face the facts, and not to rest content with merely treating what ails, after all, the accidents superimposed on the primary condition. I have

attempted, and have only very imperfectly managed, to present you with the broad aspects of the subject. Diseases of the coronary arteries present a varied picture, and certain of the more dramatic aspects are apt to blind one to the fundamental condition. These remarks, however, will have been justified if they lead to a very general discussion this forenoon.

THE ETIOLOGY OF GLAUCOMA.*

BY

W. STEWART DUKE-ELDER, M.A., D.Sc., Ph.D.,
M.D., F.R.C.S.

Assistant Ophthalmic Surgeon St. George's Hospital, Assistant
Surgeon, Royal London Ophthalmic Hospital

FROM the days when ophthalmology was first a science the etiology of glaucoma has given rise to investigations and discussions innumerable, to-day, although our knowledge has advanced, we are still quarrelling over the matter. I do not imagine for a moment that we have solved the problem, or that we have ended our quarrels, it is more likely that we are starting them afresh. But I would suggest that the trend of modern thought is throwing some new light upon the subject, and is introducing us to a completely new aspect of it. For too long the attention of investigators has been focused upon the gross pathological changes which have been observed in eyes excised for established glaucoma. The findings in these have almost invariably been interpreted as the essential causal factors in the disease, while it is more than possible that they may have been merely subsidiary causes, or even results. The essential cause is almost certainly something deeper and more subtle, and to discover its nature we shall have to go more deeply into the problem. Before we are in a position to understand pathological changes in the tension of the eye we must investigate first of all the more fundamental question of the maintenance of the intraocular pressure at its normal level and the variations to which it may be subjected under physiological conditions.

At the outset of any problem which concerns itself with the intraocular pressure the first matter to be settled is the nature of the processes controlling the formation of the aqueous humour, for these essentially must play the most predominant role in the determination of any pressure conditions, and, until agreement can be reached upon this, we can never arrive at a satisfactory or generally acceptable theory of the etiology of glaucoma. This is, indeed, the most fundamental question in the physiology of the eye, and, strangely, it is a question on which there is, as yet, a great diversity of opinion. To it I propose to suggest a very definite answer: the aqueous is not a secretion, nor is it, in normal circumstances, a transudate. It is, on the other hand, a dialysate of the capillary blood, formed by the same processes as the other tissue fluids, the only difference being that the process is modified by the relative impermeability of the ocular capillaries in order to allow the physiological requirements of the eye to be met. If the eye is to be an efficient organ of vision it is essential that its fluid contents be kept clear and practically free from colloidal micelles to allow the light to pass through undisturbed, and this is accomplished by making the capillary walls relatively impermeable. If the dioptric apparatus of the eye is to be kept properly adjusted it is essential that

the various elements in the refractive system be kept each accurately in its own proper position, a condition which is brought about by making the eyeball taut and filled with fluid under pressure, this again is accomplished, as we shall see later, by the same process of making the capillary walls relatively impermeable. The permeability of the capillary walls varies within wide limits throughout the body from organ to organ, and, in each organ, from time to time, adapting itself to suit the requirements of each peculiar case, thus, for example, in order that the functions of the liver may be carried out efficiently, the capillaries here are extremely permeable. By a modification of the same universal physiological process in the opposite direction, the eye has become biologically adapted as an organ of vision, no more simple means could have been chosen, and I know of no more beautiful example of the purposive and teleological activities of the living organism.

The argument which has led me to adopt this view would take too long to go into in detail. It is essentially a physico-chemical one, and in essence it is as follows: A dialysate in equilibrium with its parent fluid must have a very precise and definite chemical composition, it must have a very definite osmotic pressure, a definite reaction, a definite electrical potential, and there must be a definite relationship between the hydrostatic pressure at which it is maintained and that of the parent fluid.

During the past few years we have analysed the aqueous humour chemically, comparing it with the arterial and venous blood. We have measured its osmotic pressure, its electrical potential, its reaction, and determined the pressures in the chambers of the eye and in the arteries and veins. We have done it in normal conditions and in experimental variations from the normal, taking minute precautions against sources of error, and we have satisfied ourselves that the aqueous in all conditions is in complete thermo-dynamical equilibrium with the plasma—chemically, osmotically, electrically, and hydrostatically.

It must be remembered that these relationships are very complicated and very precise, and if the aqueous shows all these very complex properties, it seems illogical to deny that it is a dialysate in the absence of any definite reason to the contrary. There is no evidence, experimental or otherwise, which I know, or which I can find in the literature, and which will bear legitimate criticism, which can detract from this conclusion, to my way of thinking, at any rate, we are forced to accept it. Indeed, I think that the physico-chemical evidence which we have put forward is the most unequivocal obtainable. In the last resort the formation of the aqueous humour is a physico-chemical process. In a case such as this, anatomical evidence must be subservient to physiological findings. In much of the physiological work which has been done upon the eye confusion has arisen from a failure to appreciate the ease with which the normal equilibrium is disturbed, and many of the results lay themselves open to the criticism of reasoning from the abnormal to the normal. From this criticism a physico-chemical method of inquiry is almost entirely free. We can separate the aqueous from the influences of the complex changes which beset it *in vivo*, and in the isolation of the test tube we can determine with a very great degree of precision what the normal really is. Similarly, after introducing abnormal conditions, we can repeat the same process, and by comparison construct a coherent picture of the train of events as they have actually occurred.

The second fundamental question to be answered is that of the circulation of the aqueous humour. It is to be remembered that although I have used the word "equilibrium," the meaning is a dynamic and not a static equilibrium. All vital equilibria are of this nature. Three factors enter into the circulation of the fluid in the eye. There is in the first place a continuous metabolic interchange between the blood and the aqueous humour through the capillary walls, on either side of which the balancing hydrostatic and osmotic pressures are continually fluctuating, conditioning a flow of fluid now in one direction, now in another, so that the whole is continually renewed. Secondly, there is an internal thermal circulation caused by convection currents in the anterior chamber. More important, there is a through-and-through pressure circulation. We measured the pressure in the intrascleral

* The opening paper of a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association Cardiff 1928.

veins, and we found that, while in normal circumstances the venous pressure here was higher than the intraocular, when the intraocular pressure was raised it rose more rapidly than the venous pressure and readily exceeded it. The canal of Schlemm is in direct continuity with these venous exits, and it seems to follow that when the chamber pressure rises suddenly it exceeds the pressure here, and this excess will condition an outflow of aqueous. Such rises of pressure will be continually provided by the movements of the ocular muscles, for these have a larger effect on the tension of the eye than may be imagined. By stimulating the orbicularis to contract it has been found with a manometer inserted into the eye that pressures of the order of 40 to 60 mm. of mercury are easily attained. This action is doubtless assisted by the suction of the scleral spur described by Professor Thomson, and the result of the two factors will be an almost continuous, though very minute, circulation of fluid. This appears to act as a safety valve mechanism to maintain the intraocular pressure at its normal level, for in a globe like the eye, whose walls are feebly distensible, the expulsion of a very small quantity of fluid entails a large fall of internal pressure.

Based on our experimental studies we have thus arrived at the conclusion that the aqueous humour is in a state of continuous dynamic equilibrium with the capillary blood through the capillary walls, and that it is propelled through the eye with a small but efficient circulation. Using this as a basis for our inquiry into the cause of pathological rises of pressure, we may summarize the position from which we start under these three heads:

I. The intraocular pressure is maintained at its normal equilibrium by the height of the blood pressure in the capillaries, less the difference in osmotic pressure between the aqueous humour and the plasma.

II. Being maintained at this level the intraocular pressure may be varied:

1. By altering the equilibrium level (a) by raising the blood pressure in the capillaries, either by varying the arterial blood pressure, the venous pressure, or the local capillary pressure, (b) by varying the difference between the osmotic pressure of the plasma and the aqueous. Since the capillaries are freely permeable to crystalloids, the only common clinical condition wherein this can occur is when the colloid (protein) content of the aqueous is raised.

2. Since the sclerotic is practically non-distensible, the pressure may also be raised by increasing the volume of the contents of the eye. The only common condition wherein this occurs is when the volume of the vitreous and lens are increased by physico-chemical influences involving changes in turgidity pressure.

III. In normal circumstances these changes in pressure are to a large extent compensated by the expulsion of some of the aqueous through what we have called the safety valve mechanism of the canal of Schlemm, the lens and vitreous partially filling up the anterior chamber. The aqueous thus acts, within limits, as an elastic cushion, tending to maintain the intraocular pressure at its normal level. If, however, the swelling is great, the anterior chamber may be abolished, in which case an acute rise of tension will ensue, and again if the exit channels are rendered inefficient so that they cannot deal with an increased, or even with a normal, pressure circulation, whether it be by the formation of synechia, or by sclerosis, or by any other means, a rise in pressure will be evident at a much earlier stage. Not only will aqueous be pushed out under these conditions, but the uveal blood channels will be compressed as well, in which case the feeding arteries will pile up pressure to maintain the circulation at a higher level, until eventually their limit of effective pressure may be reached and finally overcome, in the first case the tension will be permanently raised, in the second the eye will be strangulated.

Starting, then, with these basic factors as a foundation we can proceed to apply them to the clinical condition of glaucoma.

With regard to the first of these influences—the blood pressure in the capillaries—it is evident that the influence of both the arterial and the venous pressures will be felt only

in so far as their effects are manifested in this part of the circulation. There is a large amount of statistical evidence now available, which indicates definitely that a high blood pressure in itself is not an essential, nor even an important factor in the etiology of glaucoma. The reason for this is obvious when we remember that the arterio sclerosis which usually accompanies a persistently elevated blood pressure damps down the capillary flow to such an extent that the circulation here is frequently less than normal. There is one important thing to be remembered in this connexion: in the normal individual the blood pressure is kept at a remarkably constant height, but in the high pressure subject the regulating mechanism has ceased to be adequate, and the pressure, in addition to being kept at an abnormally high level, is subject to sudden and extensive variations excited by influences so slight as would have little or no recognizable effect in the normal person. To this extent, therefore, a hypertensive diathesis will predispose to an acute crisis in the eye. The venous pressure also is effective only in as far as its influence is felt in the capillaries. Since its variations, in comparison with the arterial side of the circulation, are less adequately damped down by a vasomotor mechanism, any local interference with the venous return from the eye readily produces a rise in capillary pressure which may precipitate a glaucomatous attack. The frequency with which phlebitis and periphlebitis of the vortex veins are seen in the pathological examination of glaucomatous eyes is significant in this connexion.

There remains for consideration the essential question of the capillary pressure itself. This is controlled by many factors as yet little understood—physical, chemical, nervous, hormonal, and psychical. The tendency for the occurrence of acute glaucoma in persons of an emotional temperament or during a nervous crisis is well known, and the etiological importance of the endocrine group of glands and their association with the sympathetic nervous system is also significant. Whatever the action of these ductless glands and the sympathetic nerve—and at present it can only be expressed as a vague and indefinite association—there is no evidence that any other action than vasomotor is called into play. The essential feature seems to be a state of capillary instability and a tendency to dilatation. There may be other factors than these, possibly the accumulation of some toxic material, of the nature and action of histamine, may have some influence. It is possible that such an injurious substance might be biochemical in nature, the result of faulty metabolism, such as might upset the delicately balanced mechanism of the endocrine glands or induce a condition of sympathicotonus. Whatever it is, it is unknown, and mere speculation is useless, all that we do know and can be sure about is the essential condition of capillary instability and dilatation.

We now come to the second factor—the difference between the osmotic pressure of the aqueous humour and the blood. The osmotic pressure may be considered to be made up of two components—that of the crystalloids and that of the colloids. Since the capillary walls are freely permeable to the former, only the latter can have a permanent influence on the tension of the eye. It may be of some significance, however, that there seems to be a tendency to hypotonicity in the blood of glaucomatous patients, for on the average in these subjects the total osmotic pressure is less and the sodium diminished in comparison with normal people. I do not think, however, that the changes which have been found are great enough or constant enough to entitle us to attach much etiological importance to them, such as they are, however, they tend to indicate a change in the general metabolism. Colloids, on the other hand, are normally unable to pass the capillaries of the eye, and therefore any tendency towards an equalization of the colloid osmotic pressure of the aqueous humour and of the blood will raise the pressure level in the eye. This may be done either by lowering the concentration of colloids in the blood or by raising the colloid content of the aqueous. The first of these is again unimportant clinically, and the blood of glaucomatous patients shows no decrease in its protein content. An increase in the protein content of the aqueous humour,

however, is a common occurrence in inflammatory states and cases of intinocular haemorrhage and thrombosis wherein pathological rises of tension are by no means unknown. It is to be remembered that in these cases the influence of the increase in colloids in raising the pressure level is increased by the obstruction to the free exit of fluid which the albuminous nature of the aqueous will bring about. Finally it is to be noted that the original cause of the entrance of colloid particles into the chambers of the eye is a dilatation of the capillaries involving an increase in the permeability of their walls, and thus we return again to our first consideration, the essentially important capillary circulation.

The remaining point to consider is the matter of changes in the volume of the contents of the globe, and among these the greatest interest centres round the changes which occur in the vitreous. The general appearance of a typical glaucomatous eye, with the anterior chamber shallow and the iris and lens pushed forward, strongly suggests that one of the commonest and most important changes which occur in this disease is an increase in the volume of the vitreous. The vitreous is a gel bathed in aqueous, its chemical constitution and its structure as seen under the ultra-microscope show that it is so. The main determinant of the volume of such a system is the amount of water which it retains in association with it—that is, the degree of hydration of its colloid particles. This question of the swelling of gels is an extremely interesting one, and, unfortunately, one about which little is known at present even in the domain of pure physical chemistry. We are working on it at the moment but the experiments are long and take weeks of observation, and it is too early yet to dogmatize on the results. This much we know, however, that the pressures generated on occasion may be enormous, it is the same turgidity pressure which the Egyptians used to such good purpose in their gigantic building operations. They inserted dry wedges of wood into the crevices of rocks, and when they poured water upon them the swelling of the wood split the rock asunder. We are as yet unaware of all the factors controlling the swelling. One influence is a change in the reaction of the vitreous within the limits compatible with life: an increase of the pH causes an increase of turgidity pressure, while a decrease of pH has the opposite effect. The concentration of salts is another determining factor, and there are others about which we know less. Whatever the mechanism may be in clinical conditions, it is evident that pressures may be generated in the vitreous of sufficient magnitude to push forward the lens and the iris, to expel most of the aqueous, and to compress the uveal blood vessels to a degree which will strangulate the eye.

These then, appear to be the main mechanisms whereby the intraocular pressure may be raised. When the pressure is raised the 'pressure circulation' makes its influence more markedly felt, and by the expulsion of some of the aqueous the normal pressure equilibrium is still maintained. With the anterior chamber rendered shallow, however, the margin of safety is lowered and a comparatively small increase of pressure, one with which the normal eye could deal quite safely, becomes a source of real danger. When, in addition, the exit channels lose their efficiency, the danger becomes greater, small rises of pressure become cumulative and large rises lead to complete and sudden strangulation of the globe. Probably many influences may act, either together or severally, in obstructing these channels, the formation of peripheral synechiae, sclerosis of the pectinate ligament, the deposition of iris pigment in the meshwork of the filtration angle, a defective inward pull of the ciliary muscle, or the pressure and obstruction of a gradually growing lens—each or all of these may be present and obstruct the exit of fluid but it seems obvious that in the majority of cases their influence is adjuvant rather than primary, consequential rather than causal.

It will be realized from what has been said already that the etiology of glaucoma is not to be sought in one direction alone. The rise of pressure which we call glaucoma is a symptom common to many clinical conditions, further, there are clinical conditions wherein many of the symptoms characteristic of glaucoma are present in which no rise of

pressure can be detected. It is easy to argue that in these cases rises of pressure may occur intermittently at times when they have not been detected, but this can hardly explain the fact that it frequently happens that the progress of symptoms does not by any means run parallel with the tension, and frequently continues after its efficient operative relief. If we admit that physico-chemical changes do occur in the vitreous in some of these cases, it does not seem improbable that they continue after the mere mechanical relief of tension. After all, the normal processes in the retina are ultimately physico-chemical in nature, and it is conceivable that they also may be deranged concomitantly. There is a considerable amount of experimental evidence, for example, that scotomata can be formed by inducing retinal oedema, but this question raises matters upon which so little has been done that their discussion seems unprofitable at the present time.

Taking glaucoma, then, as a pressure symptom merely, I would suggest that the two main factors in its etiology are these: first, a derangement of the capillary circulation, involving a capillary dilatation, which produces a rise in capillary pressure, or an increased permeability of their walls allowing an excess of colloids in the fluids of the eye, secondly, changes of a physico-chemical nature in the vitreous. About the first we know little, but are rapidly learning more, about the second we know less, but are slowly finding out more. These two may act either alone or together, and their effectivity in causing a permanent rise of pressure depends directly on the efficiency of the drainage channels in the region of the angle of the iris.

MERCUROCHROME 220 SOLUBLE

JOHN EYRE, M.D., F.R.S. ED., H. E. F. NOTTON, B.Sc.,

SIR WILLIAM J. POPE, K.B.E., F.R.S.

In 1920 E. C. Whitto¹ obtained from dibromo fluorescein and mercuric acetate an insoluble amorphous substance which he regarded on analytical grounds as dibromohydroxymercuri fluorescein. He also analysed some commercial specimens of its disodium salt, "mercuromochrome 220 soluble," obtaining results which differed considerably from the theoretical values for the formula

Allowing for the water content of his samples, the agreement was better, but it is obvious that slight modifications in the method of manufacture might lead to the presence of one or more of the following impurities: (a) dibromofluorescein, (b) dibromo-*di*-hydroxymercuri-fluorescein, (c) mercuric salts, and (d) sodium acetate. Contamination with appreciable quantities of (a), (b), or (c) might considerably modify the therapeutic properties of the drug (cf. Macht and Harden²). Elementary analysis affords the only criterion of purity for a non-crystalline substance of this type, and mercury determinations alone are not sufficient for this purpose, since, for example, the presence of (b) or (c) might be masked by that of (a) or (d). Accordingly it became of interest to examine a number of commercial samples of mercuromochrome 220 more thoroughly, in order to determine first how nearly they approach in composition to the above formula, and, secondly, whether the pure specimens are pharmacologically superior to the others. The analytical results given in Table I for what purport to be four samples of the same compound are surprising. A, B, and C were obtained from ordinary trade

sources whilst D was manufactured by the published method by Messrs. British Colloids Limited

TABLE I

Mercurochrome 220 soluble	Found				Calc. for dry material		
	Hg%, ^a	Br%, ^b	Acetate % C H ₃ CO ₂	H ₂ O%	Hg%,	Br%,	CaH ₄ O ₂ %
Theoretical for CaH ₂ O ₈ Br ₂ N ₂ Hg					26.7	21.3	0.0
White (loc. cit.)	23.0				24-25		
A	37.4	10.4	6.9	8.5	40.9	11.4	7.5
B	24.1	17.4	1.2	11.3	27.2	19.6	1.3
C	28.2	23.0	2.4	10.5	31.5	25.7	2.7
D	23.2	18.8	1.5	10.5	25.0	21.0	1.6

^a By White's method (loc. cit.).

^b By the Carius method.

^c Loss of weight at 110° and 15 mm. pressure. Since all samples lost a trace of mercury under these conditions the water contents and in consequence the values for the composition of the dried products are probably rather high but in view of the relatively large discrepancies observed this is of little importance.

The high acetate content of A indicates that the insoluble intermediate from which it was prepared has been insufficiently purified by washing while the high mercury and low bromine values show that approximately 40 per cent of (b) (c), or similar impurities must be present. C, which contains, in addition to a rather large amount of acetate, more than the theoretical amount of both bromine and mercury, was probably prepared from an impure dibromofluorescein containing tetrabromofluorescein. Its composition could be imitated by adding a mixture of tribromohydroxymercuri fluorescein and dibromo-dihydroxymercuri-fluorescein to mercurochrome 220. On the other hand, samples B and D are fairly pure. Allowing for the moisture and small quantity of acetate present, D has nearly the theoretical composition.

Young White, and Swartz,² in their original paper on mercurochrome stated that 10 mg./kg. invariably killed rabbits in twenty-four hours and that *post mortem* examinations showed no gross lesions, 5 mg./kg. caused albuminuria lasting about a week. On the other hand, 10 mg./kg. were well tolerated by dogs. In later papers it is stated that this toxicity is about the same as for men.³ Other observations⁴ have been made both on animals and on men suffering from gonorrhoeal urethritis, from which the conclusions are made that the intravenous injection of mercurochrome with glucose is less toxic than mercurochrome alone, and that the therapeutic efficiency is either not affected or is even enhanced. Mercurochrome glucose therapy is strongly advocated in the treatment of all types of genito-urinary infection.⁵ Macht and his co-workers point out that mixtures of mercurochrome with glucose soon undergo a change with the precipitation of mercury, and although they agree that the glucose renders the mercurochrome less toxic, they insist that the mixture should be made immediately before injection.⁷ The same writers give evidence to show that the toxicity of mercurochrome 220 soluble is lower than has been stated: the average lethal dose for a rabbit being about 30 mg./kg. They regard their figures as due to the elimination of impurities by improving the method of production.

Clinical experience of the intravenous injection of mercurochrome in man during the past four years has impressed the fact upon one of us that a concentration of 1 per cent frequently gives rise to symptoms of mercurial poisoning as shown by acute colitis and diarrhoea with pinkish stools and that comparable doses of 0.4 per cent solution are relatively free from this objection. The present experiments were undertaken because our attention was drawn to the fact that certain samples of mercurochrome obtained in the open market were more toxic than others.

In the following toxicity experiments the injections were always made as a 0.4 per cent solution. Young adult rabbits, weighing about 1.5 to 2 kilograms were selected

for the toxicity tests, injections were made directly into the ear vein of doses varying from 10 to 27 mg. or more per kilogram of body weight.

The results at first obtained were somewhat discordant, since doses up to 25 mg./kg. of body weight were well tolerated by some animals, while similar or even smaller doses proved fatal in others in from five to ten days. The results of some experiments tabulated in ascending doses of the drug make this point clear.

TABLE II

Rabbit No.	Body Weight in Grams	Sample of Mercurochrome 220	Dose in mg./kg. of Body Weight	Loss of Weight in Grams during following 48 hours	Result.
1	3,000	A	10	Nil	Recovered
2	2,400	B	15	100	Recovered
4	2,200	A	18	401	Died (10 days)
5	2,000	B	20	300	Recovered
6	2,300	D	20	200	Recovered
7	1,850	A	22	200	Died (5 days)
9	1,900	A	25	300	Died (5 days)
10	1,750	D	27	250	Recovered
17	2,500	D	30	300	Recovered
18	2,400	D	50	400	Died (2 days)

The *post mortem* appearances observed in animals dying shortly after the intravenous injection of mercurochrome 220 were quite characteristic, and in addition to pinkish staining of the tissues and organs, especially the lungs, there was a marked excess of fluid, rose pink in colour, in the peritoneal and pleural cavities, the intensity of colour being in inverse ratio to the length of time that elapsed between injection of the drug and death.

These results suggested that the "source of origin" of the drug was of more importance than the magnitude of the dose given, within certain limits. At this stage the chemical constitution of several of the commercial brands, as already detailed, became available and on reading the results of the toxicity tests in the light of this information it was seen that toxicity depended, in part at any rate, upon the amount of mercury in the mercurochrome. This point is well shown in Chart A (showing experiments with sample A), and in Chart B, in which sample D was used.

CHART A

The same dose—that is, 25 mg. per kilogram of body weight—was used for each of six normal animals of nearly equal weight.

The results shown in tabular form may be summarized by saying that four of the rabbits in Set A died within nine days with typical *post-mortem* appearances, the rabbits in Set B showed in most cases similar initial loss of body

weight, but were otherwise unaffected, and were alive and well at the end of six weeks' observation, with but one exception, which was killed accidentally.

CHART B

Repetitions of the series of experiments set out in Chart B were made, and established the fact that the young adult rabbit would tolerate a dose of 25 mg/kg of body weight of Sample D when the concentration of the drug did not exceed 0.4 per cent. Further experiments were

CHART C

carried out to investigate the effect of employing the same dose—namely, 25 mg/kg—but increasing the concentration of mercurochrome to 1 per cent solution. A typical series of experiments is set out in Chart C, which shows clearly the marked drop in body weight (in one instance amounting to 650 grams), this was associated with obvious malaise within forty-eight hours after injection, and later a fatal termination. These observations appear to support the

clinical statement referred to, that 0.4 per cent was to be preferred to the 1 per cent concentration for intravenous injection.

INHIBITION COEFFICIENT

At this stage tests were begun with Sample D to determine the inhibition coefficient—that is to say, the percentage of the drug which, when present in the nutrient medium, is sufficient to prevent the growth and multiplication of the test bacterium. The test organisms employed were *B. coli communis* isolated from a normal stool, and a highly virulent *Streptococcus longus* (haemolyticus) isolated from a fatal case of septicaemia following an infected insect bite. In the case of *B. coli* a solution of 1 part mercurochrome in 3,500 nutrient broth (equivalent to 0.002 per cent mercury) was the smallest quantity inhibiting growth, whilst, with the more sensitive streptococcus, growth was inhibited by a 1 in 8,000 dilution (=0.0004 per cent mercury).

THERAPEUTICAL OBSERVATIONS

During the past few months, among both hospital and private patients, an unusually large number of cases of pyrexia have occurred, which when first seen were of unknown origin. These cases presented the clinical picture of septicaemia, and in a number it was decided to employ mercurochrome. For this purpose Sample D was employed, because analytical results conformed most closely to the theoretical constitution.

In many of these cases we failed to establish bacteriologically the diagnosis of septicaemia based on clinical appearances. For example, in one instance—a schoolboy, aged 13—*Streptococcus longus* and *Staphylococcus aureus* were isolated from the pus of a suppurating nodule on the shin following a septic corn, which was the starting point of the illness, but no laboratory evidence could be obtained to show that either of these organisms had entered the blood stream. The result of the injection of mercurochrome in this case was dramatic. The symptoms immediately disappeared and the patient made an uninterrupted recovery.

In the case of another schoolboy, aged 14, a "blood blister" on the heel became septic, and on the third day rigors and a temperature of 104° F occurred. On the fifth day a spreading cellulitis of both legs and the left hand and wrist necessitated incisions, an antistreptococcus serum was injected, without improving the condition. Bacteriological investigations were made on the sixth day and showed a growth of *Staphylococcus pyogenes aureus* from the various incisions, and a blood culture showed the presence of the same organism in the circulating blood. Mercurochrome 15 ccm was injected after the withdrawal of the blood for culture, and further 10 ccm doses were injected on the eighth, tenth, twelfth, and fourteenth days. The temperature fell to a lower level, but the patient's condition became very grave. Cultures of blood made on the thirtieth day were sterile. Transfusion with Group IV blood was performed on the thirty-third day, and at the same time a specimen of blood was taken for cultural purposes, this also was sterile. A further transfusion was undertaken, but the patient gradually sank. In this case mercurochrome would appear to have dealt effectively with the general septicaemia, although it did not prevent a fatal termination.

From the remaining cases, three of puerperal sepsis and one of mastoid disease have been selected for description.

In these the septicaemic nature of the disease was demonstrated by the isolation of the responsible micro-organism from the peripheral blood, and the duration of the infection was sufficiently short to permit reproduction of the temperature charts, in which the arrows indicate the injection of mercurochrome (M) or antistreptococcus serum (S).

CHART D—D M.

A married woman (D M), aged 32, required forceps delivery after a prolonged labour. Rigor and a temperature of 104° F followed on the ninth day of the puerperium when 20 ccm of an antistreptococcus serum (polyvalent) was injected without producing any fall of temperature. On the fourteenth day a blood culture produced a growth of *Streptococcus longus* (haemolyticus). 15 ccm of mercurochrome was injected at the time the blood was withdrawn. The temperature fell to normal on the following morning. After forty-eight hours the temperature rose again (to 102° F). A second dose of 15 ccm mercurochrome was given, and was followed by a fall of temperature to normal on the nineteenth day, after which convalescence progressed uninterruptedly.

In another married woman (M T) aged 27 labour was uncomplicated. She was attended by a midwife. On the third day of the puerperium there occurred a rigor with a temperature of 106° F. A blood culture gave a heavy growth of *Streptococcus longus* (haemolyticus). On the fourth day 10 ccm of mercurochrome was injected intravenously. This was followed by a fall of temperature on the following day. On the sixth day a second dose of 10 ccm of mercurochrome was injected. On the eighth day there was a sudden rise of temperature to 104° F at which point 20 ccm of mercurochrome was injected. The temperature then fell steadily and was normal on the nineteenth day.

Pyrexia of unknown origin occurred in an unmarried woman (N W) aged 23. The clinical symptoms suggested typhoid, but examination of the faeces and urine gave negative results. The serum agglutination tests against typhoid and paratyphoid bacilli were negative also up to the twenty-first day. A blood culture on the twenty-seventh day showed a heavy growth of *Streptococcus longus* (haemolyticus) within forty-eight hours. On the twenty-ninth day 20 ccm of mercurochrome was injected intravenously followed on the thirtieth day of illness by 35 ccm of mercurochrome.

chrome immediately after the withdrawal of 10 ccm of blood for culture purposes. Of this culture three tubes only containing 2 ccm, 2 ccm and 2.5 ccm respectively of blood showed *Streptococcus laqueus* (*haemolyticus*) after seventy-two hours incubation. On the thirty-third day mercurochrome (21 ccm) was again injected. A blood culture on the fortieth day was sterile. On the next day the temperature fell to normal and did not rise again.

A girl (D. L.) aged 12 contracted measles at school eight days later she complained of earache which passed off. On the fifteenth day of illness the temperature suddenly rose to 103° F. with return of the earache. On the seventeenth day the tympanum was incised and a radical mastoid operation was performed. On the twentieth day a rigor occurred and the temperature rose to 103° F. 20 ccm

mercurochrome can effect a cure in a considerable proportion of cases.

We are, of course, aware that it has been stated that animals and men who have received mercurochrome exhibit no bactericidal properties in the blood and bile. This suggests that the action of this substance is not a simple effect on the micro-organisms, but that it follows the law of chemotherapy in that it acts only through the body tissues. Bayer 205 has little apparent action on typhus *in vitro*, though it may suffice to cure animals and men suffering from *T. gambiense*.

CHART E—M. T.

CHART F—A. W.

CHART G—D. L.

of a polyvalent antistreptococcal serum was injected without obvious improvement. On the eighteenth day a blood culture showed a heavy growth of the *Streptococcus pyogenes laqueus* (*haemolyticus*). 15 ccm of mercurochrome was injected immediately after the blood had been withdrawn from the vein. On the twentieth day 12 ccm of mercurochrome was injected on the twenty-first day 10 ccm and another 10 ccm on the thirtieth day of illness. The temperature had become normal on the thirty-first day and convalescence thereafter was uninterrupted.

The general impression produced during the use of mercurochrome D was that its therapeutic activity was similar to other types of mercurochrome used during the previous four years, but that it was distinctly less toxic. It is, of course, impossible to discount entirely the operations of the long arm of coincidence. In dealing with clinical evidence of the type here presented it is equally impossible to affirm that no other treatment would have been equally effective, or, indeed, that the patients would not have done equally well without any treatment. But controlled experiments on animals have made it clear that

CONCLUSIONS

- 1 The various specimens of mercurochrome on the market differ markedly in their chemical composition.
- 2 Toxicity appears to bear a direct relationship to purity of composition.
- 3 The neutral mercurochrome approximates in its analytical results to its known chemical constitution, the better the preparation as regards therapeutic efficiency and low toxicity.

ARTIFICIAL HELIOTHERAPY IN THE ROUTINE TREATMENT OF SURGICAL TUBERCULOSIS

BY

ERIC C. MCKIE, M.B., Ch.B., F.R.C.S. Ed.

WITHIN the past decade much attention has been paid to the curative effect of sunlight and more especially to the effect of the ultra-violet rays, in many kinds of disease: rickets, marasmus, skin conditions, neurasthenia, rheumatism, hay fever, surgical tuberculosis and a host of other conditions have been described as being amenable to treatment by heliotherapy. Indeed, a reviewer of a recent publication on this subject says, "apparently there is hardly any condition for which they [the authors] fail to recommend ultra-violet light." Rollier has been the chief advocate of heliotherapy as a method of treating surgical tuberculosis, his results in alpine sanatoriums having been very successful. Owing to the lack of natural sunshine in this country artificial heliotherapy has been strongly urged as a useful and practical substitute, and many hospitals have installed artificial sunlight lamps.

Such an installation was introduced in Edinburgh City Hospital in the latter part of 1924, and since then all cases of surgical tuberculosis in which there was no definite contraindication such as pulmonary lesions or intolerance to light, have had routine heliotherapy.

Apart from the use of heliotherapy all the cases have been treated in the same manner as previously. The

treatment of the local lesions consists in putting the part as completely at rest as possible. In the case of bone and joint infection this is attained by splinting; in the case of abdominal tuberculosis and other gland lesions where such anatomical rest cannot be secured, physiological rest is as far as possible obtained. In all cases the general health of the patient has been thoroughly investigated, rest in bed is enforced during the earlier part of treatment, all foci of infection are sought out and, if possible, eradicated. The open air life of a sanatorium is insisted on and the wards are so constructed that whenever possible the patients are wheeled out in their beds into the open.

The results of treatment by heliotherapy in cases of surgical tuberculosis have been gauged hitherto chiefly by the clinical observation of individual cases, but statistics of larger series of cases are now available.

I have attempted in the following statistics to tabulate the results of the treatment of surgical tuberculosis in the Edinburgh City Hospital and to compare these with the results obtained before the introduction of heliotherapy.

The method of heliotherapy employed has been general exposure to the rays from a carbon arc lamp—using tungsten-coated carbons. The patients commenced with an exposure for ten minutes and this was increased daily by ten minutes until a daily exposure of two hours was being received. With this routine very few patients have come under my notice on whom the treatment had any deleterious effect such as skin irritation, gastro-intestinal upset, rise of temperature, loss of sleep, or general malaise. In a few

cases patients were found to be more tolerant to treatment by the mercury vapour lamp than by the carbon arc, the maximum exposure to the mercury lamp being half an hour.

The clinical result of this treatment was frequently most gratifying. I have personally observed how the general condition of the patient was improved, the muscle tone maintained or bettered, the appetite became good, the skin rapidly assumed a healthy tanned appearance, and how well the patients slept. In many instances the blood changes resultant upon the commencement of heliotherapy were studied, and in almost every case there was material increase of the red cell count and the haemoglobin content. The white cells also seemed to respond rapidly to the exhibition of ultra-violet rays, and a moderate leucocytosis has been demonstrable within a few days of the commencement of treatment. In a considerable number of cases the lymphocytes showed a relatively greater increase than the polymorphonuclear cells.

The statistics of the results of treatment have been compiled from the case records and discharge notes of the patients, and the features selected have been chosen as being most likely to exclude errors and anomalies, and so to form a sound basis upon which to draw conclusions likely to be of value. Certain facts had therefore to be considered: (1) In many of the cases it was impossible to estimate with any degree of accuracy the extent of the lesion when the patient commenced treatment. (2) Many of the patients had long-standing disease, and some showed gross deformity which demanded, if any such treatment were possible, operative intervention when the tuberculous process had quieted down. (3) The results of the treatment in hospital have been estimated by different medical officers, by some the results are claimed as cures in a higher percentage of cases than by others, who more modestly have estimated the majority of their patients as having made marked improvement or simply improvement. (4) The number of the cases is comparatively small when the different types of the disease are separately considered.

In order to exclude fallacies and arrive at sound conclusions the statistics given below have been selected as follows:

(1) The results of treatment classified as "cures" or "much improved" have been taken together in the statistics given as "very satisfactory." Further, to obtain broad general results, all cases shown as "cures," "much improved," or "improved" are classified as "satisfactory." All other cases are recorded together as "unsatisfactory."

(2) The cases have been dealt with in two age groups—up to 21 years and over 21 years, the total results for all ages have also been considered. It is hoped that by this division into age groups the majority of the frankly chronic cases will fall into the second age group, and can therefore be considered separately from the more recent cases.

(3) The average stay of the cases in each group in hospital has been approximately estimated in months.

(4) Only in those types of disease which were represented by a considerable number of cases are the figures tabulated in detail. The smaller groups of cases were also studied, and a note is added about their similarity to the other groups given.

The total number of patients with surgical tuberculosis treated before the introduction of artificial heliotherapy was 169, of whom 125 were below the age of 21. Since the artificial sunlight was introduced 153 patients have been treated, 114 being under 21 years of age. Table I shows the various types of disease treated.

TABLE I

Type of disease or site.	Cases before light treatment	Cases since light treatment.
Hip disease	26	25
Knee	7	20
Spinal	40	37
Abdominal	44	42
Glandular (cervical)	16	14
Lupus	5	3
Genito-urinary	5	2
Dactylitis	4	6
Ankle	4	2
Bone (miscellaneous)	5	4
Multiple	14	8
Joints (miscellaneous)	—	3
Other cases (eyes etc.)	3	2

Several cases where only two lesions were demonstrable have been included under two groups rather than classifying them as multiple.

The detailed analysis of all these types of disease and the results of treatment to a very great extent agree, and the salient features to which I would draw attention may best be demonstrated by the table given below.

TABLE II—Patients under 21 Years of Age

	Hips.	Spine	Knees	Abdomen	Glands
<i>Pre light Cases</i>					
No. of cases	13	28	7	40	10
Percentage very satisfactory	46.15	14.28	42.8	27.5	10
Percentage satisfactory	92.3	57.13	85.6	52.5	80
Average stay in hospital in months	10½	10½	13	4½	½
<i>Post light Cases</i>					
No. of cases	14	26	18	38	10
Percentage very satisfactory	57.14	26.92	38.9	21.05	10
Percentage satisfactory	71.43	69.3	88.9	68.42	80
Average stay in hospital in months	22	16½	16½	6½	6

In abdominal disease it was impossible to classify the different varieties of tuberculosis in the abdomen, such as plastic peritonitis, ascitic peritonitis, and tubercles mesenterica. The total figures have therefore been taken for comparison.

The patients with tuberculous cervical adenitis who came to Edinburgh City Hospital for treatment were those severer cases in which the lymph glands on both sides of the neck were extensively involved and frequently complicated by the presence of one or more sinuses. Not infrequently the patient had had one or more operations for the removal of the glands, but recurrence had followed.

Table III shows the results in all cases in those types of the disease where the figures for the total number of cases is considerably greater than for Age Group I (under 21 years) alone.

TABLE III—Total Results

	Hip	Spine	Abdomen
<i>Pre-light Cases</i>			
No. of cases	25	40	44
Percentage satisfactory	53.8	55	54.5
Average stay in hospital in months	12	11½	6
<i>Post-light Cases</i>			
No. of cases	25	37	42
Percentage satisfactory	44	69.8	64.3
Average stay in hospital in months	22½	13½	7

COMMENTS

1 The statistics of the other groups are from so few cases that it would be unwise to base any definite conclusions on them, but the results resemble closely those obtained from the larger series of cases.

2 In the figures detailed it should be noted that there has been an apparent improvement in the results obtained by the treatment of spinal disease and abdominal disease since the patients have had routine treatment by ultra-violet light. The results of treatment of hip disease by heliotherapy are apparently less satisfactory than those previously obtained. The results of treatment of disease of the knee-joint and of cervical glands show no definite difference since heliotherapy has been introduced.

3 It is to be noted also that the average duration of stay in hospital of patients in each of the five types of disease studied has materially increased. In cases of hip joint disease the average stay in hospital has been doubled, in disease of the spine the stay in hospital has been increased by six months, in knee joint cases the increase is three months, in abdominal disease two months, in glandular

disease three months' treatment is now, on the average, increased to six months. In the few instances of adults above the age of 21 the figures of the results roughly correspond with the figures of the younger patients.

CONCLUSIONS

A study of this series of cases forces me to the conclusion that the opinion which many of the earlier observers held that artificial heliotherapy would prove an almost specific treatment for cases of surgical tuberculosis has not been justified.

Without placing too great weight on any of the figures, and without seeking to arrive at final conclusions, I think it may be stated that in the series here detailed the results of cases treated by heliotherapy do not show any marked improvement over the cases of a similar nature treated without heliotherapy. There are figures which suggest that spinal disease and abdominal disease have been benefited by the ultra-violet light treatment but must we then conclude that the glandular disease in the neck and disease of the knee joint are unaffected, while disease of the hip-joint is definitely made worse by the heliotherapy? I prefer to draw the simple conclusion that on the whole the results obtained by the use of artificial heliotherapy when combined with routine sanatorium treatment and efficient local treatment, do not show any material improvement over the results obtained by treating cases by similar methods but without heliotherapy.

I believe that the reason for the increased average stay in hospital is due to the fact that the patients look so well and tanned that we are inclined to give the local lesion, however resistant to treatment, "another chance." One is almost tempted to ask the question, What would the results of the earlier cases have been if they too, had enjoyed the more prolonged sanatorium treatment?

The conclusion reached is that artificial heliotherapy does not change the fundamental principles of treatment of surgical tuberculosis. The efficient local measures taken to ensure rest and the general sanatorium treatment are the main methods to be adopted, heliotherapy is a useful aid to treatment as are many drugs. This last point I would specially emphasize because it is frequently observed that patients are moved in order that they may go to the sun room, splints and other apparatus which are usually religiously kept in place and undisturbed are then regarded as merely a nuisance and a hindrance to the transporting of the patient to the health giving rays.

I have to express my indebtedness to Mr F E Jardine for his permission to use these figures.

TUBERCULOSIS AS SEEN BY THE GENERAL PRACTITIONER*

BY

R CAMERON, M D, Ch B, D P H,
Cardiff

TUBERCULOSIS, from the general practitioner's point of view, embraces the whole range of this widespread and fatal scourge of man, from the predisposing and infecting agencies to the successful or unsuccessful termination. There is no one who has more opportunities to watch its inception and course, and there is no one who has more cause to regret lost chances of early recognition. Early diagnosis is in some cases tragically simple, in others as difficult as any which the physician has to make, since signs may be absent, and symptoms may be few, misleading, or equally applicable to other conditions of ill health. It is on early recognition that I wish to speak shortly.

It will be of service in considering our problem if one gets in focus some figures and conditions of the tuberculosis population in such a town as Cardiff and considers the relative numbers of those treated in their own homes and elsewhere. In the year 1926—according to the last available report of Dr Ralph Picken, the medical officer of health—527 new cases were ascertained by notification and otherwise, and the number of deaths was 283, both being

relatively reduced numbers for this city on account of the absence of any serious epidemic of influenza during the year.

These figures include both pulmonary and non-pulmonary cases, but they indicate only a small part of the question. The average duration of life of a phthisical person is roughly assumed to be about three years, and an actual survey of the proved cases at the end of 1926 showed that there were 1,274, while at least 150 cases of suspected tuberculosis were under the observation of the public health department.

The mortality mentioned (288) gives a tuberculosis death rate of 1.28 per 1,000, and it is important to note that the proportion of deaths from phthisis alone to deaths from all causes in Cardiff, between the ages of 16 and 65 years, was roughly 20 per cent (or one-fifth of the whole).

A further investigation revealed a serious condition, which is probably equally prevalent in other towns, and may not be well known to doctors who visit by day only 46.1 per cent of the patients slept by themselves or in a separate room, and therefore at least an equal number of contacts were exposed to infection, for eight out of every twenty-four hours, from that class of carrier who is chiefly responsible for dissemination.

It is chiefly of importance to recognize that of the 1,274 patients with frank tuberculosis known to exist in December, 1926, 96 were in institutions and the rest were in their homes. Some of these were having treatment from the general practitioner alone, or in consultation with the tuberculosis physician, but a larger number were quiescent cases. It is obviously desirable that a larger number of beds should be available in hospital for active and advanced stages of the disease.

The practitioner may therefore be said to have his full share in co-operating with the Welsh National Memorial in treatment, and it is to be hoped that he will share also, so far as lies in his power, in the responsibility for preventive measures. Those include incessant vigilance for indications of the disease, especially in the finding of any material which may be used for laboratory examination, early notification, and early consultation with the tuberculosis physician, in and behind whom lies the whole strength of the tuberculosis service and organization. This includes services of pathologist, radiographer, hospital, and sanatorium. The general practitioner can assist to improve the patient's physique, his habits, and personal hygiene, and note and try to remedy domestic conditions.

To recognize pulmonary tuberculosis when physical signs are well established and sputum abundant is to be wise after the event, to diagnose the disease at such an early period of its course as to afford a reasonable prospect of its cure is an investigation requiring many factors. Two of these are: patience to collect all symptoms which point to the condition, and such knowledge of other diseases with similar onsets as to be able to exclude them. Pottenger's classification of all the well-known symptoms into three groups seems to me of great significance when we are aiming at the diagnosis of an obscure early case. They are: (1) Pulmonary—cough, expectoration, haemoptysis, and plenisy. (2) Reflex—pain, hyperaesthesia cough and laryngeal irritation. (3) Toxic—pyrexia, malaise, loss of weight, tachycardia, anaemia, indigestion.

Any or all of these may appear in every case of phthisis, but the order of their appearance in the march of events is certainly not always the same. In some they are frankly pulmonary from the beginning—cough, sputum, or haemoptysis—though even here those obvious signs probably obscure our observation of toxic effects. In the others—the larger number and those most easily overlooked—the only evidence of tuberculosis in the early stage of the disease is toxæmia, with the train of symptoms I have already mentioned. This superficial difference between two groups is due to the one being mainly a local reaction of the pulmonary tissue to the presence of a toxic foreign substance while the other is chiefly, but not entirely, a poisoning of the tissue cells of the body generally. In reality both processes are taking place in both groups, though not in the same degree of intensity. Even in the catarrhal group physical signs are later in appearing than symptoms, while in the remaining cases reliance has to be

*Read in opening a discussion in the Section of Tuberculosis of the Annual Meeting of the British Medical Association Cardiff, 1928.

placed on symptoms alone, mainly those of toxæmia, for directing attention to the possibility of pulmonary tuberculosis. For this reason it is well to consider the various modes of onset and how these vary in detail, since one of the chief pitfalls is found in concentrating on the discovery of physical signs which probably do not yet exist.

Some cases begin without any localizing signs, and only pyrexia, loss of weight, and cardiac and muscular weakness are present. In others anaemia is marked in addition, and such are frequently treated on the lines of chlorosis. Some complain of digestive disturbance, with extreme fatigue at some part of the day. In others again the neurones seem so susceptible to the toxin that neurasthenia fills the picture. Some patients have repeated attacks of something which resembles influenza—even to the pains of limbs and back. I have personally overlooked it in patients who had attacks like ague, and who had a history of malaria during the war.

The less ambiguous onsets, of course, are those in which bronchitis, pleurisy, or hæmoptysis is the first symptom. Even when all pulmonary symptoms are latent, the persistence for a time of pyrexia, malaise, and loss of weight should point strongly to tuberculosis. It is true that, in the complete absence of sputum, without which at an early stage diagnosis is never complete, the group of blood diseases must be excluded—Addison's and the secondary anaemias, leukaemia, and even typhoid—but each of these has distinctive tests which can be easily applied.

Of the symptoms mentioned rise of temperature is perhaps the most important. A constant use of the thermometer will save many mistakes in this, as in other branches of medicine. As pyrexia may not be present to a marked degree a proper method of observation must be practised. Skin temperature has no constant reliable value, and I object personally to the routine use of the rectum. A half-minute thermometer should be placed under the tongue for at least five minutes, with the lips quite shut. If the patient takes the evening temperature himself the thermometer need not be shaken down, but may be left for the doctor to read in the morning. Occasionally it may be necessary to take it several times a day. In such circumstances, or in any case, the patient should be provided with a thermometer, and his intelligent co-operation obtained.

The maximum temperature generally occurs between 5 and 8 p.m., but in acute *miliary tuberculosis* it may be higher in the morning. Exercise augments the temperature. A long walk—say, three miles on a level road—will raise the temperature of a normal individual. In convalescence, in anaemia, and in some debilitated conditions it will raise it to 100° F., and a temperature above this is indicative of tuberculosis.

The loss of weight can easily be taken by the patient himself and recorded regularly on a card with the temperature.

An important point in considering the value of such symptoms is to elicitate a clear family and personal history—in the former, because of the influence of tissue susceptibility and still more on account of the opportunities of infection. The personal history may help when there is a record of repeated febricula, of attacks of asthma lately developed, of pleurisy however remote, and, above all, of slight or severe hæmoptysis.

As lung tissue cannot be invaded without some damage to its elasticity, even at an early stage, deficient movement on the side involved may be present to a slight degree, and the other signs which may be present are cogwheel inspiration, deficient respiratory sounds, and a slight relative dullness. The route of spread, from the apex along the anterior margin, does not help at this early stage—if indeed any signs at all are present. Radiology may be of service, especially in hilar or bronchial gland tuberculosis, but I have seen the lung screened only in the later stages when physical signs are markedly present. Like all forms of x-ray practice, it requires expert interpretation.

Of the other indirect methods of diagnosis, the complement-fixation test and the tuberculo-opsone index have fallen into disuse on account of their uncertain value. The use of tuberculin for diagnosis, whether by injection,

skin inoculation, or the conjunctival route, has never found general favour, since in each case positive results have occurred in health or in healed lesions, while in certain cases of proved disease maximum doses have failed to cause a reaction (Madsen).

I have repeatedly said that the only real proof of tuberculosis is in producing the bacillus. This is comparatively easy when the case is one with cough and sputum, hæmoptysis, or pleural effusion. In all these material can and should be got which will reveal the organism on examination or animal injection. There is sometimes difficulty in obtaining such material in the other group I have attempted to indicate, but it can be had eventually in every case. In some cases of fibroid phthisis in children, in the insane, and in the closed bronchial gland cases it may also take time and trouble, but it is the duty of the physician to find it as early as possible. Since the tubercle bacillus is not destroyed by the gastric juice or by the putrefactive state of the intestine, it may be recovered from the faeces when sputum has been swallowed.

Next as an aid to diagnosis come symptoms, but these are present at an earlier period. They also continue throughout the course of the disease as the only real evidence of its activity and intensity. They are present from the beginning, but are frequently overlooked or ascribed to some other cause.

Physical signs and radiography are of service in judging the extent and progress of the pulmonary changes, but may occasionally support at an early stage the supposition which the symptoms imply. Family and personal history are valuable for corroborating other evidence.

The Sections.

SUMMARY OF PROCEEDINGS

(Continued from page 209)

SECTION OF THE HISTORY OF MEDICINE.

Wednesday, July 25th

IDEAS REGARDING THE NATURE AND TREATMENT OF DROPSY.

THE President of the Section, Mr. W. G. SPENCER, in opening the proceedings, referred to the fact that this was only the second year that the Section had been held, it was fitting that the inaugural meeting should have been held in Edinburgh, since the Edinburgh and Leith Division had been largely instrumental in bringing it to birth. Dr. J. D. COMRIE (Edinburgh) read a paper on the history of dropsy, which is published elsewhere in this issue (p. 229).

Discussing Dr. Comrie's paper Dr. J. A. NIXON (Bristol) referred to watery oedema or famine dropsy, first mentioned by Hesiod and subsequently by other ancient writers. In the Middle Ages the earliest allusion to it was in 1523, when it ravaged the French army besieging Naples. It was also noted among the defenders in the siege of Breda in 1625, and it was mentioned by Sydenham "Where scurvy leaves off, dropsy begins." In 1762 Lind quoted a letter from a British naval surgeon, necessarily familiar with scurvy, who notes as a novelty a form in which dropsy was an outstanding feature. Kollerthauer saw famine dropsy during Napoleon's retreat from Moscow. In 1847 the Medical Society of Ghent first defined its clinical characteristics—a form of oedema associated with bradycardia, polyuria, and asthenia, unattended by albuminuria, cardiac dilatation, or nourishment. The speaker quoted an interesting case of official stupidity exhibited by Sir Richard Temple during the Indian famine of 1877-78. This official mistook for fat the dropsical swellings produced by the cutting down of the diet of the people. His medical officer, Cornish, pointed out his chief's mistake, with the result that Temple received the K.C.S.I., while Cornish's name was struck out of the list of officers to be decorated for fighting the famine! Famine dropsy was reported in Lille in 1914 among the French civilians during the German occupation. Since then it had been heard of more and more

among prisoners of war and in some of the famine-stricken populations of Middle and Eastern Europe. The speaker had brought to his notice a curious instance of the difficulty of diagnosing these nutritional dropsies during the war. A form of dropsy was occasionally exhibited by Indian labour troops, was it beri-beri? Army officials, always ashamed of the presence of such nutritional diseases reflecting on the quality of the ration supplied, argued that it could not be beri-beri, because it did not occur among certain tribes—men fed in exactly the same way forming another detachment. However, after much difficulty the explanation was found in the confession that the immune tribesmen had, without authority to do so, supplemented their ration with rats eaten raw! The President referred to the surgical treatment of dropsy since the days when as a physician's clerk, at St Bartholomew's, he had seen cases treated by paracentesis, a painful and hazardous procedure, or alternatively by the use of Southey's tubes, with the danger of fatal erysipelas. He desired to say in word in favour of the old Talma Morrison operation of omentopexy, which had taught them much about the condition of the abdominal contents in dropsy, and had been occasionally successful in prolonging life for a considerable time. In a case in which he had been associated with de Havilland Hall he had, with the aid of omentopexy and other surgical procedures, lengthened a woman's life for at least four years, only to lose her from an overdose of some narcotic. Dr BUIST called the attention of the Section to the fact that percussion was used long before Auenbrugger.

WELSH PHYSICIANS AND THE RENAISSANCE.

Dr I. ROLAND WILLIAMS (Maenlochlog) read a paper on Welsh physicians and the Renaissance. He said that at that period there were two conflicting traditions: (1) of culture derived from the older universities, (2) a popular tradition, of course the older, originating in various superstitions and undoubtedly preoccupied with sheer filth and ordure as therapeutic agents. Traces of it still survived even to this day in out-of-the-way parts of the country. Another feature of this system was the fantastic employment of drugs of animal origin—for example, "eye of newt and toe of frog," etc. Even now goose grease and salt bacon had a distinct vogue. Such survivals showed how deep-rooted these beliefs and practices must have been, and by contrast therewith it was best possible to estimate the profound influence of the new learning on the practice of medicine in Wales. The physicians who came under it were stomped especially by the breadth of their cultural outlook. They laboured to extend the boundaries of learning in other subjects while pursuing their practice. Among the most notable of these Welsh physicians were Alexander Read, by birth a Scotsman, but who practised on the Welsh border, Robert Records of Tenby also a great mathematician, born in 1510, a Fellow of All Souls in 1531, at one time Comptroller of the Mint and inventor of the sign of equality (=). His chief medical work was *The Urinal of Physic*. Humphrey Lloyd of Denbigh (1527), who also studied at Oxford, was private physician to the Chancellor of the University. His chief medical works were *The Judgment of Urine* and *The Treasury of Health*. Among the early translators of the classics was a Welsh physician, Thomas Phaer, who translated nine books of the Aeneid into English verse. Many of the Welsh grammarians were also physicians, chief among them was John Dafydd Rhys, who, after studying for many years in Italy and writing a favourite textbook on the Italian language, returned to Wales to practise amid the sombre environment of the Brecknock Beacons. He was just such a personality as Browning has depicted in "The Grammarian's Funeral."

The sectional secretary, Dr FREDERICK, in the absence of the author (Dr DIVERRES) read the paper on the Welsh physician in the Middle Ages. He dealt with his subject from its Druidical beginnings, through the Roman era down to the end of the twelfth century, illustrating his remarks by quotations from Welsh manuscripts. Dr ROLAND WILLIAMS, in the discussion, said that the codifiers of the Welsh laws were preoccupied with the medico-legal aspects of medicine—for example assessments of damages and of the value of medical services.

History of Scarlet Fever

Dr J. D. ROLLSTON read a paper on the history of scarlet fever. He said that it was only since the time of J. P. Ingrassias (1510-80) that scarlet fever had begun to be separated from other exanthemata. He called it "rossalia" or "rosania." Next Baillon described the principal varieties of the disease in 1575. In 1600 (circa) Daniel Sennert identified an epidemic in Wittenberg with "rossalia," and gave a good account of its varieties. Sydenham was supposed to have been the first to use the term "scarlatina," but the term "scarlett fever" is also found in Pepys. Sydenham appeared only to have been acquainted with a very mild form of the disease but possibly when Sydenham saw a bad case he failed to recognize it as such. However, he established it as a separate disease. In the eighteenth century many epidemics were described by various writers. Rosen von Rosenstein was one of the first to mention the possibility of a non-eruptive scarlet fever. There was undoubtedly a considerable increase in the disease during the last quarter of the eighteenth century. Many observers during the nineteenth century had shown the tendency of the disease to give rise to malignant outbreaks succeeded by mild ones (Graves, Bretonneau, etc.). Bretonneau also clearly differentiated scarlatina anginosa from diphtheria. During the nineteenth century the disease appeared for the first time in several new parts of the globe (Madaira, South America, and other places). The mortality from scarlet fever in this country reached its maximum in 1863, since when there had been a steady decline. Since the war there had been a great advance in our scientific knowledge of scarlet fever. Klein had suggested a streptococcal origin for scarlet fever in 1887, but it was not until 1923 that George and Gladys Dick had proved it and had subsequently evolved the Dick test and a curative serum.

The President, in the course of the discussion, recalled that between 1885 and 1887 Klein had worked on scarlet fever attributed to cow's milk, and had cultivated the cow's milk and set up surgical scarlet fever in calves. He had had the opportunity of watching Klein's work. "Surgical scarlet fever" was a recognized condition occurring after injury especially burns and scalds. Although not so common as formerly, he noted that in 1927 there were references to post-operative scarlet fever in infants, surgical scarlet fever, and to traumatic scarlet fever.

History of Cinchona

Mr C. J. S. THOMPSON read a communication on the history and lore of cinchona. He said that the mass of material was so great that he would briefly consider it in three aspects: traditional, empirical, and chemical. Its origin was very obscure, it was doubtful if it was known to the Indians, with the possible exception of the Malocotos tribe, a chief of which was the first recorded to have used the drug in 1600 in curing a Jesuit missionary. A Spanish functionary is said to have been cured by it in 1630. However, since its local name was "quina-quina," signifying "bark of barks" it was probable that some special value was attached to it. In modern times, on the contrary, Indians had exhibited prejudice against it. It was introduced into Europe by the Countess of Chinchona, wife of one of the viceroys of Peru, in 1639, after she had just been cured of ague by it, administered by her physician. Dr Juan de Vega. She returned to Spain in 1640 and brought a quantity with her. In 1659 Roland Sturm wrote a treatise on it, whence it appears to have been known in Rome, Brussels, and Antwerp. There was considerable dispute as to its efficacy. It was introduced into England in 1655 as the Jesuit's powder, and was soon after exploited by Robert Talbot who made his name and fortune by employing it as a secret remedy after his death his methods were published. Among his patients were Charles II and the Dauphin of France. The first appearance of Peruvian bark in regular medicine was in 1677 in the *London Pharmacopoeia*. La Condamine, a Frenchman, was the first to attempt to bring the plant to Europe, and it was first described botanically by Linnaeus in 1753. In 1839 Roxley suggested the introduction of cinchona into India and ultimately this was effected, but the Dutch managed to grow it in Java earlier.

The Dutch were indebted to an Englishman, Robert Ledger, for their first seeds. On the chemical side Gomez of Lisbon was the first to isolate the basic properties of the drug. In 1820 French chemists isolated quinine and cinchonine. Since then more than thirty alkaloids had been found in it, but the most important by far was quinine.

SECTION OF LARYNGOLOGY AND OTOTOLOGY

Wednesday, July 25th

CHRONIC ETHMOIDITIS

THE President of the Section, Dr D R PATERSON (Cardiff) took the chair at the opening meeting. Dr ROSS HALL, SKILLERN (Philadelphia), who read the opening paper on "Chronic ethmoiditis: its treatment, conservative and surgical," divided chronic ethmoiditis into the suppurative and non-suppurative types. In the first the infection was characterized by the formation and exudation of a purulent secretion, the secretion sometimes being thick and almost pure pus, at others thin and almost watery. The non-suppurative type was characterized by polypoid hypertrophies and the polyp formation was unaccompanied by true leucocytic pus. He thought that all now recognized the hyperplastic ethmoiditis as a separate pathological entity in contradistinction to the earlier known suppurative infection. When the two conditions were found combined this was due to the suppuration being superimposed on the hyperplasia, in fact, the greater the polyposis the more likely that the commoner forms of saprophytic organisms would find a suitable medium for their growth. He then detailed a classification of the ethmoidal labyrinth infections and discussed the various types. In the treatment of ethmoidal disease it was essential to provide for aeration and drainage. He had long believed that removing all infected tissue was as unnecessary as it was radical, that with proper assistance nature would do much to bring about a resolution. In a case of simple catarrhal infection characterized by mild headache, stuffy nose, and a fairly constant mucoid discharge with very little to show on rhinoscopic examination, he found the removal of the swollen middle turbinate almost a *sine qua non* to treatment. The purpose of this was to allow for ventilation and permit the application of cotton poultices saturated with a silver preparation in glycerin. In cases of combined suppuration affecting the entire labyrinth he was quite satisfied that nothing but a so-called complete extirpation was of any avail. He described, with lantern slides, various operations for ethmoidal extirpation.

Mr WALTER G. HOWARTH approached the subject from the point of view of one who believed in the efficacy of an external operation in certain cases, and suggested that this method of treatment might be made use of more often. In chronic generalized polyposis improvement or cure might follow simple lavage and general hygiene. These cases were not usually seen until the cells themselves had become involved, and he did not then think that removal of the middle turbinate alone was of much use. The bone beneath must also be removed. In chronic suppuration with no polyp, but with crust formation and discharge, it was often found that after apparently thorough intranasal operative treatment there arose a doubt as to whether benefit was likely to accrue from any further operation. After many years he had come to the conclusion that some external operation assured complete exposure. He had employed the external operation for fifteen years, and had definitely noticed that ethmoidal suppuration was the key to disease of the frontal sinus. The approach from outside gave a more perfect exposure of all the ethmoidal cells, was not dangerous, and in actual practice the scar produced was almost negligible. He did not guarantee even this method to expose all the ethmoidal cells in every case.

The President emphasized conservative treatment. Looking over a few of his own cases he discovered some in which he had urged operation years ago but had been refused (both polypoid and suppurative type), and since some of these cases had done remarkably well. It was well known that many patients did very well by relying on regular removal of the polyp, which were obvious on rhinoscopy,

and therefore easy to attack. With regard to Mr Howarth's remarks about the external operation he cordially agreed, but thought that there was some risk involved.

Mr E B WAGGETT drew attention to the association of ethmoiditis and antritis. He considered that more attention should be paid to the bulla of the ethmoid, and in all cases operated upon this cavity should be opened.

Mr HERBERT TILLEY insisted that it was necessary to use the endoscope for the examination of the posterior ethmoidal cells in all cases. He considered the endoscope an essential instrument in carrying out a thorough examination of the nose. He also stated that in all cases of chronic rhinitis he was in the habit of aspirating the antial cavity for the purposes of diagnosis. Mr WILLIAM HILL, on the other hand, advocated more restraint in the matter of puncturing antra and exploring cavities in the course of a routine examination. He did not see much difference between the treatment described by Dr Skillern and that which had been constantly practised in this country during the last ten years.

Dr P WATSON-WILLIAMS (Bristol) considered that pathologically the non-suppurative and suppurative types described by Professor Skillern and Mr Howarth as separate entities were really the result of the same type of infection. He agreed that the treatment of nasal infection by means of tampon applications was likely to find more favour in the future, but he thought that tamponage with vaccines rich in the specific antibodies would prove more useful. As regards diagnosis of the position of the infected cells, he thought his own method of aspiration by means of suitable trocars and cannulas more accurate than those mentioned by Dr Skillern. He had long ago given up all external operations, as he considered the ethmoidal cells, etc., could be cleared up in all cases equally well by intranasal operations.

Mr SYME (Glasgow) believed that many cases of ethmoidal infection were not cured owing to the fact that the antrum and frontal sinus were not excluded as a focus of infection. He did not think that the external operation presented any advantages as regards complete removal of the diseased area when compared with the intranasal approach. Mr C A S RIDEAU (Portsmouth) drew attention to the constancy of pain between the eyes in cases of posterior ethmoidal suppuration. He was an advocate of the open operation in suitable cases, and stated that he had found that the maxillary antra were infected in practically all cases of infective ethmoiditis. Dr COVENS (Philadelphia) touched on the question of vaccine therapy as applied to nasal infections of the chronic type. He stated that in America the present tendency was not to rely greatly on this form of treatment. Mr HOGAN (Cork) upheld the methods of nasal examination recommended by Dr Watson-Williams, and drew attention to the advantages he had found accrued from the use of his transantral method of approaching the ethmoidal cells. Dr LOGAN TURNER (Edinburgh) thought that Mr Howarth's method of approach conformed more to the general principles of surgical treatment. He was himself personally convinced that infection could spread along the olfactory nerve sheaths to the meninges, and said that in the Edinburgh museum there were three specimens demonstrating this both macroscopically and microscopically.

Optic Neuritis due to Sphenoidal Sinusitis

Dr P WATSON-WILLIAMS read a short paper on a case of optic neuritis due to sphenoidal sinusitis located by the differential exploratory test and cured. He first mentioned that in cases of optic neuritis the saving of sight depended upon the drainage and cure of the focal infection. He reiterated the fact that the anatomy of the posterior ethmoidal cells and the sphenoidal sinus is very irregular. He then described a case of optic neuritis which had no nasal signs or symptoms of any kind. On examination by his usual technique both sphenoidal sinuses were found to be sterile, but the antrum and ethmoidal cells were infected on one side. Eventually, on more careful examination, a small left sphenoidal sinus was found, which had been missed on the first examination. It was filled with mucus and blood. Both sphenoidal sinuses

were opened and drained, and within three months the eye symptoms had disappeared. The object of reading the paper was to draw attention to the necessity of thoroughly investigating the nasal cavities in all cases of optic neuritis.

SECTION OF ORTHOPAEDICS

Wednesday July 25th

LOW BACKACHE AND SCIATICA

The first meeting of the Orthopaedic Section was held on Wednesday July 25th, with the President Sir JOHN LANN-THOMAS, K.B.E., in the chair. Mr W. A. COCHRANE (Edinburgh) opened a discussion on low back ache and sciatica. Mr Cochrane began by pointing out the frequency with which this complaint occurred, and estimated that back strains and injuries accounted for 20 per cent of all accidents in some large industrial concerns. He emphasized the difficulties of diagnosis and the importance of a routine clinical examination of every patient as well as the necessity for good stereoscopic roentgen photographs or ruling these, a lateral as well as an anterior-posterior view. He thought that milkinging was less common than many suspected, and that "compensation-itis" was often the direct result of delayed diagnosis and treatment; this delay produced a nervous mental state which would never have arisen if prompt treatment had been instituted. He classified the patients into five groups—namely (1) acute traumatic strain, (2) general postural strain, (3) lumbo-sacral strain, (4) sacro-iliac strain, (5) combined pelvic joint strain. Each of these required its own appropriate treatment. Mr Cochrane made a separate reference to "idiopathic sciatica," and referred to Professor Putti's views, with which he did not entirely agree, as he thought that certain abnormalities were more common and more important in producing "sciatica" than the discrepancies between the intervertebral canal and the nerve trunk. The speaker showed a number of excellent lantern slides illustrating the types of brel which often give rise to pain. He indicated how some could be diagnosed by inspection of the patient's back, and how others were revealed by x-rays or comparison with abnormal anatomical specimens.

Mr P. JENNER VERRALL, who had been investigating the backache which so often occurs in pregnant women thought that such patients were more orthopaedic than gynaecological and that the ideal attack was by a combination of the resources of these two branches of surgery. Similar pain was often due to a loaded rectum referred through the third sacral nerve. Apart from these causes he cited the following types: (1) Diminished lordosis with tenderness over the origin of the erector spinae and diminished postural tone of this muscle. This was due to prolonged strain from stooping, or from increased abdominal weight from pregnancy, abdominal fat or lorded and prolapsed intestine. (2) Increased lordosis, persisting after parturition leading to lessened tone of the abdominal muscles, and lumbo-sacral strain, curable by a temporary belt and exercises. (3) Increased lordosis, due to a flexed hip on one or both sides, often due to chronic inflammation or irritation of the ilio-psoas by the caecal appendix or sigmoid and curable by attention to the primary cause. (4) True sacro-iliac pain, characterized by the now recognized symptoms. Sacro-iliac subluxation after pregnancy was a real entity; these joints relaxed during the latter months of pregnancy, and their tone was restored *post partum* with that of the uterus. Too early strain would lead to weakness and displacement, an adequate rest time after parturition was indicated. A further pregnancy followed by a well-managed puerperium, would cure as in the case of the uterus but otherwise a suitable belt and pad, with or without mobilization, would meet the case. Somewhat similar relaxation occurred at the menstrual periods.

Mr D. MCNEAL AITKEN was impressed by the way in which the subject had been thrown open by previous speakers, especially in so far as they had emphasized the great importance of posture. He believed that "crush fractures" of the vertebrae were common and that such injuries might occur even in children when the vertebrae were largely cartilaginous. He thought that the quadratus lumborum was a muscle peculiarly liable to strain, and that it was

probably a factor in the production of one group of painful back. He agreed with previous speakers in their advocacy of prompt support and rest in accordance with the principles laid down so long ago by Hilton, and pointed out that muscular re-education was, as had already been stated by the opener, a very important part of the later treatment of such patients. Mr B. WHITCHURCH HOWELL spoke of the frequency of "lumbago" amongst the industrial classes. He treated simple cases of recent trauma of lumbar region by immobilization for a short time but mobilized the chronic cases under a general anaesthetic. He was against operative removal of a sacralized transverse process of the fifth lumbar vertebra in the present state of anatomical knowledge but thought exploration of the sciatic nerve gave very good results in stubborn cases of true sciatica. Mr A. ROCKY-JONES emphasized the importance of exactly locating the area of tenderness to pressure in any painful back. He described the physical signs on which he was accustomed to rely in diagnosing between the various groups, and spoke of certain difficulties he had found in the reading of x-rays of the lower third of the spine. Mr ALAN H. TODD thought that belts were at best a temporary remedy, and that the training of the abdominal muscles was a very important step towards permanent natural support. He believed that patients with injured backs suffered from the lack of medical men and masseuses possessed of special experience in this work, and that there would be little progress in this direction until hospital beds were available for such patients.

Dr MANNING WHITE (Nantwich) referred to possible infective causes, and Mr WATERFIELD (Banbury) and Dr SOLLY (Harrogate) followed. Dr MORRIS (Birmingham) considered that overwork and general debility played a large part in producing "lumbago." He had found Iaston's syrup a simple but effective remedy in several tired patients. The President spoke briefly of his past experiences in Cardiff, and then called on Mr COCHRANE to reply.

SECTION OF PREVENTIVE MEDICINE

Wednesday July 25th

CONTROL OF INFECTIOUS DISEASES

Dr F. COLSTON WILLIAMS (Cardiff), President of the Section in a brief opening address, said that the present age was characterized by much impatience on the part of the public in respect of the application of the results of modern scientific investigation to the prevention of disease. It was the duty of the administrator to glean what was most useful out of the results of such research, and then to apply it with firmness and tact. Dr L. J. RACHMAN (Geneva), opened a discussion on the value of the present methods of control of infectious diseases with special reference to small-pox, and exhibited many valuable statistical diagrams. He showed how the incidence in various countries had changed, and discussed the probable existence of two distinct types of this disease. Dr J. MIDDLETON MARTIN (Gloucester) remarked that in a short time great advances had been made in the knowledge of infectious processes and it was the more curious that the infecting agents of some of the common diseases remained unknown. Dr T. FURSTACE HILL (Durham) referred to the heavy incidence of small-pox in the county of Durham but said that the case mortality had only been at the rate of 0.27. It was therefore, a mild type of the disease but he would not agree that it was specifically different from ordinary small-pox, or that it was right to relax efforts to control it on account of cost. Dr R. P. GARNOW (Cheshire) expressed his belief that small-pox as now seen was a different disease from the severe form. People preferred to have it with the comforts of a hospital for a few weeks to undergoing the inconvenience of vaccination. If cases were isolated at home it would encourage vaccination. Dr R. BRUCE LOW said the proper method of prevention were clearly laid down in the memorandum of the Ministry of Health, but they were not always adequately carried out, especially in rural districts.

Sir MALCOLM WATSON (Malaya) said there were not two or three ways of controlling small-pox, but one, and that was adequate vaccination, which had entirely stamped out

small-pox in Malaya Dr BRINDLEY (Derby) referred to the great practical difficulty of actually tracing contacts, and Dr KERR (Newcastle) thought the difficulties would be lessened if vaccination were modified so as to produce a less severe reaction Dr PICKER (Cardiff) said there were different degrees in other diseases, such as enteric fever, but this did not justify the modification of methods of prevention in regard to them

Dr R A O'BRIEN (Beckenham), in a paper on the control of diphtheria and scarlet fever, dealt mainly with the practical steps advisable, and indicated possible improvements in testing an immunization He concluded that, as regards diphtheria, an almost complete control was now possible, and emphasized the serious risk entailed by the undetected "profuse" carrier Further investigation in scarlet fever was required before a similar satisfactory state could be reached Dr J GRAHAM FORBES discussed the recent progress made in this country in the application of the Schick and Dick tests and active immunization A number of statistical tables were shown as lantern slides

Dr B A I PETERS (Bristol) said that the Schick test had proved successful at the Westham Hospital, Bristol, in 98 per cent of cases, though it was not infallible in face of a very virulent strain of the organism Dr E H R HARRIES (Birmingham) gave the warning that the Schick test would not eliminate the immune carrier Surgical treatment of the naso-pharynx in suitable cases had reduced their percentage of return cases from 2.9 to 0.2 Dr GOODALL said he was convinced of the value of active immunization in protecting nursing staffs against diphtheria, but he had had no experience of the method in connexion with scarlet fever

SECTION OF MEDICINE

Thursday, July 26th

PREVENTION AND TREATMENT OF DIPHTHERIA

Dr J D ROLLESTON, in opening a discussion on the prevention and treatment of diphtheria, said it was doubtful whether isolation had reduced the incidence of the disease No uniformly successful method had been found for putting an end to the carrier state, the persistence of which was usually due to local infection in the tonsils, adenoids, and nasal sinuses, success in dealing with it had resulted chiefly from surgical attention to these factors Passive immunization by injection of antitoxin conferred an immediate immunity of short duration, usually not longer than four weeks, 500 units, irrespective of the age of the subject, might be given for this purpose either subcutaneously or intravenously, oral administration was useless As a general rule this method should be confined to children, and, in his opinion, in hospitals and in well-to-do families, where close observation could be kept up it was rarely necessary Active immunization, on the other hand, conferred a much more durable and possibly a permanent immunity Nowadays it was customary to dispense with a preliminary Schick test in children under 6 years old on the assumption that the large majority were susceptible, but in adults, who were much more likely to react severely to immunizing doses, a preliminary test was indispensable No fatal accidents following active immunization had occurred in this country, but the local and constitutional disturbances were occasionally severe With regard to treatment, it was usual in the Metropolitan Asylums Board hospitals to employ large doses of antitoxin—4,000 to 8,000 units for mild faucial or nasal cases, 12,000 to 16,000 units for moderate attacks, and 24,000 units, repeated if necessary, for severe cases The intramuscular route was unquestionably the best Antitoxin must, of course, be given at the earliest possible moment on clinical manifestations, independently of the bacteriological report He denounced the suggestion that unless given by the fifth day of the disease it was useless The chief advance in recent years in serum treatment was the introduction of the refined serum, the use of which had reduced the incidence of rashes and other unpleasant sequelae to a minimum Next to early antitoxin administration the most important item in treatment was the enforcement of rest in bed

Dr GRAHAM FORBES emphasized the need for keeping the

carrier under close observation, and in this respect a watch on the nasal passages was of prime importance Control of diphtheria by bacteriological methods by swabbing was unreliable, and dependence on immunization was more and more clearly indicated With regard to the evidence in favour of preventive inoculation, he pointed out that in self-contained communities, such as hospital and residential institutions, this rested on a sure foundation, but proof of undoubted benefit from extensive preventive inoculation in a community, such as that of New York, was still awaited For the acceptance of diphtheria in a Schick negative reactor it was essential that (1) the result of the test should be indubitable, (2) the clinical and bacteriological diagnosis must be firmly established, (3) the test must be carried out by an expert Park had stated that he had never seen a case in which these conditions were fulfilled With regard to the occurrence of diphtheria in those who had received the full immunizing course of three doses, he expressed the need for retesting three to four months after the third dose to show whether the original positive reactor had become immune as shown by a negative re-test Dr FORBES asked whether the presence of a large number of protected individuals who might become potential carriers would constitute a source of danger for the non-immunized In the immunization of some 50,000 individuals in this country, involving at least 300,000 injections, no known harmful effect had been reported

Dr E W GOODALL discussed the advantages of the various routes for the administration of antitoxin Undoubtedly the effect of the antitoxin was obtained more quickly by the intravenous route, but allergic reactions were an objection, and in children it might be very difficult to get the serum into the vein The clinical results obtained were insufficiently striking to commend the practice as a routine method, and it should be reserved for severe cases The antitoxin was absorbed more quickly if injected intramuscularly than by the subcutaneous route, and the former route should therefore be adopted in cases intermediate between the severe and the benign With regard to dosage, after experimenting with various doses up to 100,000 units, he had decided that a dose of 30,000 was the limit beyond which it was unnecessary to go The earlier the patient was brought under treatment the more satisfactory were the results, but a severe case was not necessarily a late case, nor was a late case necessarily a severe one, each must be judged entirely on its clinical merits apart from its duration, and so long as any membrane was present antitoxin should be given Dr Goodall emphasized, in conclusion, the folly of waiting for the result of a bacteriological examination in a suspicious case, and his advice was that the culture swab should be abandoned altogether

Dr JOHN MCGARRITY (Cardiff) related the results of the immunization experiments carried out in conjunction with Dr KER in Edinburgh in 1922-24, and the subsequent work that had been carried on there since Over 6,000 children had been immunized without any ill effects With adults, however, considerable local reaction and constitutional disturbance was apt to occur, this was noticed amongst those who had a pseudo-Schick reaction, and since the use of toxoid-antitoxin had been general it was unusual to get reactions even in an adult He maintained that there was now clear evidence that the practice of immunization was perfectly safe He recalled the evidence as to its efficacy contained in the recently published report of the medical officer of health for Edinburgh, and said that in Cardiff no child who had been a negative Schick reactor when tested in the schools had up to date developed diphtheria Dr McGarrity advocated strongly the routine administration of an initial intravenous injection of antitoxin in severe cases, following it up subsequently with intramuscular doses In ordinary moderate cases this procedure was unnecessary, intramuscular injections being quite sufficient The diphtheria patient must be kept flat in bed until all danger of paralysis or heart failure had passed The treatment of heart failure, as McEneaney had said, lay in its prevention by early dosage with sufficient antitoxin, but if it showed itself he had found caffeine sodium salicylate and camphor the best drugs to use, to be given hypodermically in from 1/2 to 2-grain doses according to

age every two to four hours. He had a liking for the use of alcohol in small doses and adrenalin chloride at the beginning was sometimes useful, but it must be stopped at once if any irregularity of the heart occurred.

Dr BLFASK (Aldershot) said that the public authorities now paid for every swab taken, and the results had been most satisfactory. Many early cases were diagnosed in this way before clinical manifestations of diphtheria had appeared, and cases left until too late had disappeared. This method of careful and early swabbing gave much more practical results than could be hoped for by immunization methods as yet. Dr G. W. GOONANT also advocated the use of early and adequate bacteriological examination, it was essential to give antitoxin on the earliest clinical manifestation of diphtheria, even in face of a negative swab. Many early cases of diphtheria presenting themselves as simple tonsillitis would be missed until a late period but for bacteriological examination.

SECTIONS OF SURGERY AND OF RADIOLOGY AND PHYSIO THERAPEUTICS

Thursday, July 26th

THE FALLACY OF X RAYS IN ABDOMINAL DIAGNOSIS

Mr HERBERT J. PATERSON, in opening this discussion, said that radiology must not be used as a substitute for clinical observation, but merely as an aid to diagnosis. The main fallacies could be placed in four groups. Those incidental to x rays were well exemplified in the use of a barium meal to ascertain the degree of intestinal stasis (the use of charcoal gave different results), and the numerous misinterpretations of local spasms of the alimentary tract. Fallacies due to technique were illustrated by the importance of taking exposures in varying positions in the cases of gastric or duodenal ulcers, the ulcers otherwise being often missed. Again, errors in diagnosis occurred if the stomach were not adequately filled with the opaque meal. Occasionally a radiological examination might divert attention from the disease suspected. Fallacies due to misinterpretation were numerous. Examples were mentioned—namely, scybalous masses indistinguishable from shadows due to gall stones, and the misinterpretation of phleboliths and calcareous glands as ureteric stones. Impacted faeces might show a well marked filling defect with a barium enema, even after apparent clearing out of the bowels, and on re-examination later might show a normal colon. Another possible fallacy was that the impacted faeces might be due to an early carcinoma, which would not be confirmed by x-ray examination until it was too far advanced for surgical treatment. Diagnosis of adhesions, especially in the right iliac fossa, was rarely confirmed at operation. Mr PATERSON said that radiology showed apparent healing of a gastric ulcer in three to four weeks of intensive alkaline treatment. He stated emphatically that the pathological evidence was against this rapid change, and that the x-ray interpretation was wrong and fallacious. Radiological evidence as a gauge of the progress of the healing of a gastric ulcer was obviously useless and misleading. In abdominal diagnosis radiology was still in its infancy, but its value was unquestionable, and would be even greater in the future when experience had taught the correct interpretations of what was seen. If the radiological findings did not support the clinical signs and symptoms they should be disregarded, and an operation should not be performed only on purely radiological diagnosis.

Dr F. HERNIMAN-JOHNSON said that the barium meal localized any stasis to a particular site in the gastrointestinal tract, and that the method of administration of charcoal, as suggested by Mr PATERSON, was of no real value. A good practical rule was to disregard stasis up to twenty-four hours. When spasm, as shown by the barium meal, resisted all changes of posture, was present for long periods, and was not affected by belladonna given in large doses, it was nearly always evidence of organic disease of some portion of the alimentary tract or its offshoot, the gall-bladder. Spasm of some part of the tract might constitute the disease. Thus the demonstration of spasm played an important part in abdominal diagnosis by radiology. Partial examination of the abdomen might lead to misdirection, but a complete one should not do so. Errors

in interpretation were then fully discussed, and the speaker referred to the cases described by Mr PATERSON. It was necessary to distinguish between radiological findings, and deductions. Regarding the diagnosis of adhesions, manipulations under the screen were unreliable, it was better to repeat the examination in a few hours.

Dr ARTHUR F. HURST said that charcoal was useless as a means of demonstrating stasis. It was most important to know the point in the alimentary tract at which stasis occurred. He now never diagnosed gastric or duodenal ulcer without x-ray evidence given by a competent radiologist. Radiological evidence was very important in the investigation of healing of ulcers. X-ray findings should not necessarily agree with clinical findings, to be of any value. Slides were shown of healing ulcers, and the speaker pointed out the possibility of misinterpretation of a shadow due to diverticulum of the cardiac region of the stomach. Dr HURST stated that inflation of the bowel with air helped in the radiological diagnosis of adhesions. He concluded by saying that the radiologist could not be expected to work alone, but must have the co-operation of his colleagues.

Mr W. McADAM ECCLES pointed out that diagnosis of disease of the appendix by a barium meal was often fallacious, and was the outcome of incomplete x-ray investigation. He referred to cases of young women with right iliac pain who were really suffering from spasm of the pelvic colon giving rise to distension and pain on the right side. A barium enema would clear up the diagnosis.

Mr FULLERTON (Belfast) said that the physician, surgeon, radiologist, and pathologist should piece together their various findings to reach the correct diagnosis. He referred to the fallacies of x-ray examination in cases of urinary calculus, and said that the radiologist must not be expected to work unaided. Sir WILLIAM DE COURCY WHIFFLER (Dublin) advised the radiologist to attend the operations or obtain a detailed report of them. He warned radiologists not to give too dogmatic a report when dealing with cases from busy country practitioners. He added that a photograph should be taken before the introduction of bismuth, to discover the presence of anything abnormal, particularly in the urinary tract. All subsequent pictures must be taken in exactly the same position.

Mr RENDLE SHORT (Bristol) said that screening was very important. A barium meal often missed a carcinoma of the colon and a barium enema was not infallible. Exploration was justified when symptoms were reasonably suggestive and when x-ray diagnosis had been obtained. He had found that when symptoms and signs disagreed with radiological findings the latter were more often correct. Dr CANDY (Newport) described the difficulties which had to be overcome. The radiologist needed the clinical history and findings and opportunity for complete investigation just as much as the physician and surgeon. Professor A. W. SHEEN (Cardiff) said that co-operation was absolutely necessary. The value of negative results was pointed out. Referring to barium enemata, he said that they were fallacious because often there was not enough fluid injected, and secondly the fluid did not show an early growth. Dr OWEN RHYS (Cardiff) was pleased to hear that the surgeons recommended co-operation with the radiologists and that they were ready to share the responsibilities.

SECTION OF SURGERY

Thursday July 26th

THE TREATMENT OF GANGRENE

Mr W. SIMPSON HANDLEY who opened this discussion, limited his remarks to the vasomotor surgery of gangrene. He said that Leriche, in order to divide the sympathetic nerve supply to an artery removed the outer coat of the vessel for some distance. This operation of arterial sympathectomy had met with success in Leriche's hands in cases of (1) causalgia after war wounds, (2) the painful pre-gangrenous crises caused by obliterative endarteritis, (3) painful neuropathic syndromes following bruises and wounds, especially of the finger, hand, palm, or sole of the foot, (4) Raynaud's disease, (5) sometimes in painful stumps, (6) in muscular spasms secondary to war wounds,

(7) in trophoedema, (8) in trophic ulcers, but here the result might only be temporary. The operation was not recommended for actual scirrhous gangrene. Mr Handley stated that his method of alcohol injection was a definite advance on Leriche's operation. He said that in certain cases it prevented threatened gangrene and arrested the spread of senile gangrene. It sometimes averted the necessity for an amputation, or permitted a lower amputation to be performed. The technique of the operation was simple: after exposure of the artery in Hunter's canal, 2 to 3 minims of alcohol were injected at four equidistant points around the artery. After the injection was completed a white band, about half an inch wide, was seen around the vessel, but there was no constriction. The immediate effect was vaso-dilatation with no preceding vaso-constriction. Mr Handley strongly recommended his method for threatened or incipient gangrene, especially during the prodromal stage, when pallor, coldness, and severe pains were present. In cases of extensive gangrene, owing to the risk of toxic absorption from the increased blood supply following the operation, the speaker did not recommend the injection unless it was followed immediately by a low amputation. The operation was contraindicated in cases of gangrene associated with already existing vaso-dilatation. It was useless for Buerger's disease and of doubtful value in Raynaud's disease. The greatest use of vasomotor surgery was during the pre-gangrenous period, though in the early stages of gangrene the vaso-dilatation of the vessels limited the spread and restored vitality to dying tissues.

Mr PHILIP TURNER limited his remarks to the clinical aspects of periarterial sympathectomy. Clinical observations certainly showed that there was improvement in the circulation and an increase in the amount of blood in the distal part of the limb. He gave a brief summary of eight cases of senile gangrene—two treated by sympathectomy and six treated by alcohol injection. He had not used these methods for threatened gangrene, but he thought in such cases that care should be taken that the pain was due to arterial disease and not to other causes. Mr Turner said that periarterial sympathectomy did not replace amputation, but was a valuable additional method of treatment. He agreed that it was difficult in some cases and that alcohol injection was a better method.

Mr E G SLESINGER referred to Langley's work on the course of the vaso-constrictor fibres, and said that the spinal nerves carried these fibres to the vessels. These nerves gave off branches to the vessel at different levels along the length of the artery. If this were true, periarterial sympathectomy could not produce vaso-dilatation in the distal part of the limb. The speaker thought, therefore, that the operation of periarterial sympathectomy destroyed the afferent fibres and so interrupted the reflex arc and abolished the painful spasms. Pain was relieved even if there was no improvement in the circulation. He had never seen the initial vaso-constriction described by Sampson Handley and Leriche. He favoured periarterial sympathectomy, since alcohol injection could not be controlled, and sympathectomy admitted of microscopic examination of the resected plexus. Referring to the classification of arterial disease, Mr Slesinger said that the functional type, which included Raynaud's disease and erythromelalgia, was only relieved by excision of the sympathetic ganglia concerned, while the organic type, senile arteritis, etc., was improved by periarterial sympathectomy and pain was generally relieved.

Mr W A COCKRANE (Edinburgh) said that he dissected the main artery for about two inches and swabbed the surface with gauze. No actual stripping was done. The operation gave good results in early cases of senile gangrene, and in promoting healing of varicose ulcers. No good effect had been obtained with perforating ulcers of the foot and endarteritis obliterans. In view of the good results obtained by Brown and Adson in endarteritis obliterans by sympathetic ramisection, it seemed that arteries had a segmental nerve supply. If this was so, the question arose as to the best site for the operation on the sympathetic path.

Sir WILLIAM WHEELER (Dublin) had found that neither alcohol injections nor periarterial sympathectomy improved

cases of thrombo-angitis obliterans. He disagreed with Mr Slesinger's statements that pain was relieved in such cases and that initial vaso-constriction did not occur. Care should be taken to divide all fibres. If the artery was sclerosed he employed alcohol injections. Varicose ulcers had healed rapidly after this method. Mr BROCKMAN (Sheffield) agreed that alcohol injection was easier and safer than periarterial sympathectomy. Sympathectomy presented real difficulties, especially when the vessel was hard. He thought that Mr Slesinger's explanation of the results of sympathectomy was wrong and that probably pain had a chemical basis in the periphery of the nerve. The speaker stated that a toxic patient could be improved in health by this method, in preparation for secondary amputation.

Mr SAMPSON HANDLEY, replying, said that the operation was of use for threatened gangrene, but was of no use for endarteritis obliterans. He could not explain the lack of initial vaso-constriction in Mr Slesinger's case, and regarding his physiological theory he said that it required laboratory confirmation.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Thursday, July 26th

DIAGNOSIS AND TREATMENT OF STERILITY

Mr A E GILES opened a discussion on the diagnosis and treatment of sterility. He indicated the main lines of investigation necessary to ascertain whether the anatomical and physiological factors concerned were normal and healthy. He considered that marked retroversion and acute anteversion of the uterus undoubtedly produced a hindrance to conception, and that correction of these conditions frequently led to fertility. The patency of the tubes could be ascertained by the insufflation method. At this point their range of investigation ceased. They had no means of discovering whether healthy ova were maturing. He outlined the treatment called for in the different types of case. In under-development he spoke favourably of thyroid extract and hypodermic injections of freshly prepared ovarian substance. If the patient were too stout weight should be reduced by diminishing the total intake of food. If the vagina were too narrow a plastic operation might effect a remedy, in pinhole cervix dilatation to a moderate degree might be successful. Noxious discharges should be treated by curetting and the application of tincture of iodine. In tubal obstruction surgical measures were called for. Finally, in cases of endocrine inadequacy, laboratory investigations into basal metabolism and blood morphology might lead to a scientific and successful line of treatment.

Mr SIDNEY FORSDIKE reviewed those cases in which no gross lesion was present and no lesion sufficient to stamp it as the cause of the condition. He stated that 25 per cent of childless marriages were due to the condition of the husband. It was rare to obtain any living spermatozoa from the vagina, as they were rapidly killed, but living spermatozoa could be recovered from the cervical canal within a few hours of coitus. Investigation should then be transferred to the uterus, tubes, and ovaries. The possible lines of inquiry were exploration of the uterus by dilatation and curettage, inflation of the uterus and tubes, investigation of the uterus and tubes by means of opaque bodies, and exploration of the pelvis by laparotomy. Mr Forsdike outlined the methods of inflation which he employed. He did not consider that plastic operations carried out on the narrow part of the tube were justifiable. Obstruction at the fimbriated extremity was a different matter, though even then opinion should be guarded, as he had found that out of twenty cases, eleven were closed again within three months of operation. He described the results he had obtained in a hundred cases of inflation of the uterus and tubes, from which it would appear that 31 per cent of apparently normal women became pregnant after inflation. After inflation with closed tubes operation was to be recommended if an injection of lipiodol demonstrated the obstruction to be in the ampulla. In regard to the ovaries, cysts of one or both ovaries, in contradistinction to cystic ovaries, did present opportunities of success in cases of sterility. He had operated upon six cases, in four of which pregnancy occurred within three months. It was difficult to under-

stand or explain these cases, but there was no doubt that the relationship was cause and effect. There remained the type of case when an apparently healthy man was married to an apparently normal woman and yet the marriage was barren. He considered these cases to be due to the coincidence of minor defects in both parties, resulting in combined relative sterility.

Mr KENNETH WALKER discussed the diagnosis and treatment of sterility in the male. Of 57 cases of men who had been referred to him by gynaecologists only 25 could be considered entirely normal, 18 out of the 32 being completely sterile. Speaking generally, sterility in the male was more frequently the result of acquired conditions than of congenital abnormalities, and in the production of these venereal disease played the chief part. He then passed in review the conditions which might affect spermatogenesis, pointing out that the spermatogenic function of the testicle was far more sensitive to outside influence than was that of internal secretion. Thus mild infections, heat, and diet had been shown to affect the formation of healthy spermatozoa. Mr Walker then discussed artificial insemination; this procedure very rarely appeared to succeed in the human species, whereas in veterinary practice success was frequently achieved. He suggested that they should take a hint from the veterinary surgeons and change their technique. In regard to treatment, surgery offered very little help in cases of stenosis either of the epididymis or of the ejaculatory ducts. In cases of aspermatogenesis improvement in the general health undoubtedly increased fertility. Septic foci should be searched for and treated. Endocrine therapy was worth trying, anterior lobe pituitary extract being the most useful product, and it should be given over a period of six months. In elucidating the physiology of impregnation the gynaecologist and the genito-urinary surgeon must work together as colleagues engaged on a single task.

Professor BECKWITH WHITEHOUSE (Birmingham) said that in dealing with sterility it was striking how difficult it was to secure pregnancy when everything seemed favourable. They must concentrate in future on physiological function. Reference to questions of diet and sunlight were very interesting. In regard to anatomical defect, he was sorry that Dr Forsdike was so pessimistic in regard to plastic work. He did not think that they had yet arrived at the proper technique. In his cases he had injected lipiodol directly into the tube from the abdomen. He was a strong advocate of lipiodol, it prevented formation of adhesions. It was extraordinary how pregnancy might occur even after removal of the tubes. He had failed with artificial insemination, for the reasons, he thought, put forward by Mr Walker. At present he was advising swabbing the vagina with a diphtheria swab after coitus and painting the endometrium directly with the swab.

Professor VAUDESICAL (Paris) agreed with Dr Giles. Nil nocere was the best motto in dealing with these cases. Pregnancy might occur at the most unexpected moment. In retroversion the position of the os was of no interest in the determination of sterility. Insufflation and injection of lipiodol must be a recognized method, but must be used with great circumspection. He preferred lipiodol as one could see what one was doing. He thought that undoubtedly pregnancy occurred after lipiodol, and as the result of its use, and not from coincidence. Dr MARGARET BISCOE was much impressed with the frequency in which blocked tubes occurred in sterility. Nothing abnormal might be felt on vaginal examination. Blockage of tubes was much more common than was generally realized. She always used an anaesthetic during insufflation because of the possibility of spasm of the tube occurring. She had not yet used lipiodol, but had decided to do so. In the majority of cases stenosis was found to occur at the amputated extremity. Obesity was an important factor, and corpus luteum extract sometimes was very successful in such cases. Dr BUIST (Dundee) thought that the treatment for many cases of sterility could be summed up by the old-fashioned saying, "Live on a shilling a day and earn it." Vaginismus might be prevented by proper ante-marital education. He had personally experienced distress after taking a dose of ovarian extract by the mouth. Dr

FRANKLIN MURRAY (Newcastle) had examined a number of cases of sterility. In nearly one half he had found definite evidence of infection of some sort. He had obtained a positive test of sealed tubes in one-third of the cases. He always gave an anaesthetic. He did not advise laparotomy at once on discovering a sealed tube, his rule was to wait and see for a time. He carried out the test again before advising opening the abdomen. In five out of six cases he had explored he found evidence of tubercle, and he would not hesitate to open the abdomen where the history suggested tuberculosis. He had on two occasions embedded ovarian tissue in the uterine wall, but he could not say whether it was of value or not. Mr FREDERICK ENOE (Birmingham) said that sterility might be due to the ovum escaping at the wrong time, owing possibly to the density of the tunica albuginea. Dr GRAY WARD (New York) spoke on the subject of stimulation of the ovaries by x rays. This method was being used more and more in America. Only a very mild dose was employed.

The PRESIDENT thought that progress was being made in this subject. Twenty years ago the importance of the male factor was not appreciated. Rubin had pointed out in the beginning that one test was not sufficient for giving a definite diagnosis. The use of lipiodol was a distinct advance. Another method was to insufflate a barium powder into the cervix. A few hours later it would be found in the tubes, and later still in the peritoneal cavity. No operation should be advised without investigation. Insufflation might work by dislodging some small plug of mucus. He had never practised artificial insemination, but he thought that success might follow if the technique of the veterinary surgeons was adopted. Irregularity of menstruation was not necessarily a cause of sterility, but a harmless method like stimulating with x rays should certainly be tried in certain cases.

In replying to the discussion Mr GILES did not think that artificial insemination was called for in cases where normal intercourse was possible. He strongly advocated early operation in appendicitis as, if pelvic peritonitis occurred, the danger of the tubes becoming blocked was very great. Mr FORDSIKE agreed that lipiodol prevented the formation of adhesions. With a pressure of 300 mm of mercury in a conscious patient he was prepared to give a definite diagnosis of tubal patency on one test alone. He did not agree with using anaesthesia in insufflating. He did not believe that incompatibility existed. Mr KENNETH WALKER relied a great deal upon the veterinary surgeons in helping him to elucidate problems, and they did not believe in incompatibility.

MYOMECTOMY DURING PREGNANCY

Professor VAUDESICAL (Paris) in his paper on myomectomy during pregnancy, said that judgement and common sense were required in the selection of each case, as only exceptionally was that operation during pregnancy the correct procedure. The indications for operation, in his opinion, were (1) when the fibroid was large, was diagnosed early during pregnancy before the third month, and when the swelling of the tumour was easily distinguishable from that of the uterus, (2) if, at any time, unmistakable signs of necrobiosis appeared, (3) axial torsion of the uterus or partial retroversion due to the presence of a fibroid, (4) torsion of the pedicle, (5) when the fibroid was causing pressure upon neighbouring structures. He described the main points to be attended to in operative technique, and quoted his statistics for a period of six years. In 38 per cent of cases operated on myomectomy was performed, and in 62 per cent it was found necessary to do hysterectomy. Operative interference during pregnancy should therefore be postponed as long as possible in order to obtain a living child.

Mr GILES had performed some twenty myomectomies during pregnancy, seventeen cases going to full term. The indications for operation were of great importance. If the chances of a natural delivery appeared to be reasonably good he was disposed to wait if necessary dealing with the fibroids after parturition. He would prefer always to do a hysterectomy after involution than when the uterus was large from pregnancy. If symptoms of necrobiosis occurred then operation was called for. In properly selected cases

myomectomy in pregnancy was a very successful operation. Mr L. C. RIVETT thought there were two indications—the size of the fibroid and necrobiosis. He did not think that myomectomy should be attempted when performing a Caesarean section. He considered that myomectomy was called for if symptoms of red degeneration occurred. Dr FARQUHAR MURRAY (Newcastle) advised expectant methods in cases of red degeneration. Operation during pregnancy should be avoided where possible. Professor BECKWITH WHITEHOUSE (Birmingham) did not dread myomectomy since he commenced doing Caesarean sections under spinal anaesthesia, haemorrhage under these conditions being practically negligible. Mr THOMSON COLLINS (Cardiff) always removed fibroids of any size discovered at any period of pregnancy.

SECTION OF PATHOLOGY AND BACTERIOLOGY

Thursday, July 26th

THE INTESTINAL FLORA IN HEALTH AND CHRONIC DISEASE

SIR THOMAS HOUSTON occupied the chair during this session. Professor CRICKSHANK (Aberdeen), who opened the discussion, traced the development of the intestinal flora of the adult from that of the suckling. The main types of organism normally found were described, together with the effects on their numerical proportions which could be exerted by variations in diet. The experimental arguments for and against the hypothesis of toxin absorption by the intact intestinal mucous membrane were discussed. By the employment of appropriate selective cultural methods it was possible to isolate bacteria sometimes alleged to be pathogenic from the faeces of healthy individuals. The absence of a standard cultural technique, the multifarious action of such factors as diet, and the great variety of bacteria concerned, made it impossible to define a "normal" condition of the intestinal flora, and dangerous to accept the frequently alleged pathogenicity of individual organisms in given cases: this was usually unsubstantiated by any specific reaction, or by any form of proof acceptable as demonstrating the causal connexion of the organism with the disease.

Sir THOMAS HORDER, whose communication was read in his absence, regarded some of the criteria used to determine pathogenicity of intestinal bacteria as inadequate. Three such criteria were instance—namely, the so-called excessive proportion of streptococci, the late lactose-fermenting type of coliform bacillus, and what was known as the serum-resisting type of coliform bacillus. The setting up of such arbitrary standards of pathogenicity as these was apt to mislead the general practitioner.

Professor J. H. DIBLE (Cardiff), in dealing with the coliform group, observed that different techniques yielded a variety of results in culture, and emphasized the need of a standard and generally recognized method of cultivating faeces. In three series of over a hundred cases each in which non-lactose-fermenting coliform bacilli appeared in the faeces he had studied the incidence of Morgan's bacillus No. 1, and found that its frequency increased with the proportion of cases in which he found dysentery bacilli. In a study of the enterococcus he had compared the aesculin fermentation test with the heat-resisting property of the organism and found that they tallied in 206 out of 248 strains. In studying haemolysis among faecal streptococci in thirty-eight stools he had found streptococci exhibiting haemolysis on blood agar in thirteen cases, but of these only eight were truly haemolytic, as evidenced by haemolysin production in a fluid medium. He regarded the closed loop experiments described by Professor Crickshank as inconclusive, in that in clinical intestinal obstruction there was an increased degree of absorption from the bowel. He had noticed that those who knew least about intestinal bacteriology were most impressed by the phenomena of supposed auto-intoxication, the variable factors concerned were so numerous that he regarded conclusions drawn from an isolated stool examination as valueless. Dr A. F. S. SLADDEN (Swansea) observed that no branch of applied bacteriology stood in greater need of clarification. It was sometimes forgotten that the intestinal contents were outside the tissues: thus swabs taken by the sigmoidoscope from ulcers,

and mucus or muco-pus found in faeces, were likely to yield more informative cultural results than the faecal material itself, in that they represented a nearer approach to the tissues of the body. Cultivation of a specimen of faeces innocent of mucus or other abnormal element was a procedure he regarded with both distaste and mistrust. A new and simple cultural technique was necessary, and a better test of pathogenicity than agglutination of the organism by the patient's serum. The discovery of a similar organism in the urine sometimes helped to confirm the significance of bacteria found in the faeces. Dr L. P. GARRON discussed the significance of variations in the streptococcal content of the faeces. A quantitative method of examination was essential. The principal factor concerned was diet; this could be demonstrated both by feeding normal individuals with excessive and diminished carbohydrates, and by examining the faeces of carnivorous animals and diabetics, both showing few streptococci on a low carbohydrate diet, and herbivorous animals, such as the horse, and milk-fed infants, in whom the opposite phenomena was presented. In forty-two cases of normal subjects or patients suffering from no recognized intestinal abnormality the average proportion of streptococci in plate culture had been 36 per cent., in thirty-five cases of colitis, arthritis, pernicious anaemia, and alleged auto-intoxication the average proportion was 38.3 per cent. He submitted that the pathogenic significance of an "excess" of streptococci was unproved. Dr A. P. CAWADIAS drew a clinical distinction between the saccharolytic type of auto-intoxication, with diarrhoea, flatulence, acid light-coloured stools, and a positive Schmidt test, and the proteolytic type, with alkaline offensive dark brown stools and definite signs of toxic absorption. He urged that the significance of any bacteriological abnormality could only be determined by considering in conjunction with it the clinical features of the case. Dr BANCROFT ANDERSON asked what treatment was available when the patient's antibody-producing mechanism had broken down: was a vitamin deficiency concerned in this process?

Sir THOMAS HOUSTON (Belfast) believed that clinicians would never be persuaded that the intestinal bacteria were not concerned in chronic disease, an important fact in this connexion was the frequent occurrence of chronic infections in various parts of the body after abdominal operations. He himself had particularly studied the enterococcus, and believed it capable of assuming pathogenic importance both on the ground that it was sometimes to be found in other parts of the body, such as the urinary tract, the tonsil, and the post-nasal space, and because in many cases agglutinins for this organism were to be found in the blood. Anomalous results in agglutination experiments with the enterococcus were apparently due to the existence of both rough and smooth strains. The diplococcus alleged by Baigún of the Mayo Clinic to be the causative agent in ulcerative colitis was a non-mannite fermenting enterococcus.

Professor CRICKSHANK, replying, repeated that, in his opinion, the intact mucosa was an efficient barrier to toxic and bacterial absorption. An aspect of vaccine treatment in cases of supposed auto-intoxication which was sometimes forgotten was that antibody formation afforded no antidote to absorbed chemical products. He was convinced that special methods would reveal so-called abnormal organisms in the faeces of healthy individuals. The enterococcus was a widely distributed organism, discoverable in dust, in the mouth, the tonsil, and elsewhere, and without more specific evidence of its pathogenic action in the cases quoted by Sir Thomas Houston he could not accept the conclusions drawn from them.

SECTION OF PUBLIC HEALTH

Thursday, July 26th

THE TEACHING OF HYGIENE

THE President, Dr R. M. F. PICKEN (Cardiff) called on Dr W. W. JAMESON (medical officer of health, Hornsey) to open the discussion on the teaching of hygiene. Dr JAMESON dealt in an illuminating way with the training of health workers, the teaching of hygiene to school children, and public education in health, his remarks being mainly concerned with principles. He pleaded for the better education in this respect of medical students and of teachers in

schools. The part played by capable sanitary inspectors could not be overestimated, and broadcast talks were still insufficiently employed. More continuity in the various methods adopted was very desirable.

In the discussion that followed Dr H B BRACKENBURY explained that the General Medical Council had no power over the teaching bodies except in the limited sense that it could approve their curriculum and inspect their examinations. As Dr Jameson had mentioned, there were over a hundred voluntary organizations all engaged in promoting health teaching and propaganda, all doing the same thing and each with its own president and secretary. Perhaps the first step that should be taken would be to abolish these. The real places for education in matters of health were the school and the consulting room of the private practitioner. The education given in the schools was carried back to the parents, but the instruction should be given by the school teacher.

Dr LLEWELLYN WILLIAMS (Welsh Board of Health) claimed that the instruction given in the past was responsible for much of the improvement that had already taken place in the public health. The teaching of hygiene to medical students was accordingly of first-rate importance. The general practitioner was the person most likely to see disease in its early stages, and the proper person to educate the public in preventive measures. Dr OLIVE WHEELER (professor of education, University College of South Wales) emphasized the necessity of co-operation between educational and medical authorities. In the educational world there was a reaction against the over-intellectualism of the past, and the necessity of physical training and physical fitness was more fully realized. Professor KERR (Newcastle) said the teaching of hygiene was side-tracked in many medical schools, especially in London. He thought more attention was given to it in the provincial medical schools, and described the very full course of instruction given at Dundee University.

Mr J MACKENZIE (secretary, Industrial Health Education Society) described the work of his society and the great expansion that had taken place in a few years. There was a demand from the workers for such instruction, and they were entitled to have it. Dr FRANK JONES (county medical officer of health, Cardigan) thought that hygiene was not a new subject in the schools. It had been taught, but the teaching had been a failure because the teachers themselves were ignorant of the basic principles on which hygiene was founded. He described the methods adopted at Aberystwyth for the training of teachers as instructors in hygiene. Mr J CHEW (organizing secretary, Central Council for Health Education) said that the general practitioner was essentially a missionary of health and the panel doctor should more and more become a teacher of health. Mr BOYDAS (secretary for education, Dental Board of the United Kingdom) describing the educational work of his board, said he often noticed that local authorities had a scheme for instruction on dental hygiene on paper, but frequently it did not get beyond that stage. He generally found that the medical officer and the school medical officer were in sympathy with the aims of the board, but it was not always so with the education authorities.

Professor F E WYNNE (medical officer of health, Sheffield) said the most important thing in the training of the medical student was to disabuse his mind of the prevalent idea that hygiene was a matter of drains and smells. In too many cases in "non-provided" schools the teaching of hygiene to the scholars was a farce, owing to the abominable sanitary conditions of the schools themselves. Dr ROBB (medical superintendent, Belfast Fever Hospital) advocated an interchange of nurses between the general hospitals and the fever hospitals. Dr E COLSTON WILLIAMS (county medical officer, Glamorgan) said the general practitioner was already a very busy man, and it was difficult for him to devote much time to instruction in face of the demand of his patients for treatment.

Other speakers in the discussion included Dr Carstairs Douglas of Anderson College, Glasgow, Dr Leopoldt school medical officer of Capo Colony, Dr Hamilton of Newport, Dr Letitia Fairfield, London, Mrs Neville Rolfe, Dr Goodall and Dr T Evans, Swansea.

SECTION OF ORTHOPAEDICS

Thursday, July 26th

VOLKMANN'S ISCHAEMIC CONTRACTURE

Sir JOHN LYNN-THOMAS, President of the Section, took the chair at first, and later was followed in it by Mr P JENNER VERNALL. Sir ROBERT JONES (Liverpool) read a paper on Volkmann's ischaemic contracture, with special reference to treatment. The paper was described by later speakers as a classical monograph, and will be published in a subsequent number of the *Journal*. Sir Robert discussed the etiology of the condition, and referred to the experimental work of Brooks and Jepson on dogs. He considered that the essential factor in prophylaxis was immediate and complete reduction of fractures in the region of the elbow-joint. Open operation should be reserved for those rare occasions when reduction by manipulation was impossible. Treatment, when ischaemia was once established, ought to aim at the removal of all compression, either within or without the affected limb. He described and demonstrated his well known method of gradual and progressive splinting of these contractures, beginning distally at the terminal interphalangeal joint. His large experience showed that even the most unpromising limbs would partially recover over a period of years under appropriate treatment. Sir Robert Jones insisted that Volkmann's ischaemic contracture sometimes occurred without any suspicion of carelessness on the part of the attending practitioner, but that it was never justifiable to handage or strap the limb in anatomically full flexion. He had always used the "collar and cuff" method, and thought it excellent when once any bone deformity present had been corrected. He concluded by emphasizing the necessity for x-ray pictures of these patients and a medical defence society for their doctors.

Mr W ROWLEY BRISTOW described briefly the electrical reactions of the affected muscles. He thought that an operation to restore tactile and thermal sensation was justified in a bad case when nerves were damaged, even if there could be no hope of muscular recovery. Mr D McCRAE AITKEN said that it was important to realize that the circulation would often return when twisted blood vessels resumed their normal position after the reduction of a supracondylar fracture. He wondered whether the contracture was susceptible of a physiological explanation. Mr HARRY PLATT (Manchester) looked to anatomy rather than to physiology to provide the explanation. He thought that extravasated blood in a "closed box" of inter-fascial plane might induce venous stasis. Mr D STEWART MIDDLETON (Edinburgh) interestingly elaborated this point. He had been able to confirm Brooks's observations. Mr Middleton showed by a diagram that the superficial and deep veins of the forearm converged to a key-point in the ante-cubital fossa. He thought that even a small haematoma in this area might be a much more frequent cause of ischaemic contracture than splints or tight bandages. Mr ALAN H TODD described two patients in whom the contracture appeared, though no splints or bandages had been used. He thought it important from a medico-legal standpoint that every occurrence of this kind should be published. A considerable percentage of the recorded cases of Volkmann's contracture followed fractures of both bones of the forearm. He believed that it was necessary to correct the mistaken and dangerous idea that both anterior and posterior splints were necessary in treating fractures near the elbow-joint, he never used more than one. The best way of treating fracture of both forearm bones was by means of the "supination bar" plaster. Mr B WHITCROFT HOWELL mentioned several illustrative cases and discussed treatment from both operative and non-operative aspects. Mr P JENNER VERNALL and Mr A ROCYN JONES both spoke briefly, and Sir ROBERT JONES, in his reply, expressed the general opinion that the discussion had been particularly instructive.

The meeting then adjourned to a local cinema, where the President (Sir John Lynn Thomas) demonstrated films which he had caused to be made. The first of these showed special methods of muscle re-education for limbless men at the Prince of Wales Hospital, Cardiff. The second showed Sir Robert Jones successively reducing a Colles's fracture, putting up a fractured femur, and using Thomas's wrench on an example of club-foot.

SECTION OF OPHTHALMOLOGY

Thursday, July 26th

THE ETIOLOGY OF GLAUCOMA

Mr W S DUKE-ELDEN, in opening the discussion on glaucoma, reviewed the modern theory that the aqueous humour was a dialysate from the blood plasma and gave an account of this theory of the mechanism of the maintenance of the normal intraocular pressure. He then suggested the various ways in which the intraocular pressure was concerned and considered these in relation to the etiology of glaucoma. The paper is printed in full at page 236.

Mr THOMSON HENDERSON (Nottingham), in a spirited address, attacked the theory of dialysis. He did not believe that this was the main factor in the formation of the aqueous fluid. He contended that the eye and the cranium were alike closed boxes with unyielding capsules with total fixed volume, in which the fluid contents varied with the pressure in the exit veins, that being the lowest circulatory pressure possible. This was shown by ophthalmoscopic observation as regards the eye, the slightest digital pressure obliterating the retinal veins. The intraocular pressure, therefore, was not lower than the venous exit pressure, as Mr Duke Elden affirmed. Nor did he (the speaker) believe that accommodation or movements of the external muscles affected the intraocular pressure. He did not think that for a simple dialysis the ciliary body and choroidal plexus would have such complicated structures. He believed that the two primary influences in the production of glaucoma were (1) predisposing, a pathological excess of the physiological sclerosis of the ciliiform ligament, and (2) a strangling of the intraocular circulation between the unyielding capsule of the eye and the incompressible fluid contents of vitreous and aqueous. The train which fired the explosive glaucomatous attack was laid by the general systemic circulation.

Mr VISNOR HANZMAN expressed his admiration for the excellence of work by the anatomist and the physiologist on the etiology of glaucoma in recent years. In the small cockpit of the eye there was being fought out another round between structure and function. Each of them owned a bias towards one or other of these observations, and this would in some measure determine their practice. Admitting the correctness of the experimental evidence of the physiologists and the probable truth of their deductions, there would be a tendency to exploit treatment of medical order for the relief and control of this disease, and there was no one who would not desire this outcome. But the demonstration of structure was so striking, and the superior effectiveness of surgical measures so evident, that for himself he found structure and surgery influenced him most in his teaching of post-graduate students.

Mr A W ORMOND thanked the opener for his experimental observations, which he had found useful in his comprehension of glaucoma. Acute glaucoma had been produced by Dale by introduction of histamine, and possibly it might also be produced by toxins. All the signs of inflammatory glaucoma might be explained on the capillary dilatation theory. He mentioned Bayliss's experiments on the swelling of colloidal gels by the action of acids and alkalis. He believed that there were many types of glaucoma, with varying causes, and he expressed some doubt as to whether the more chronic types were due to alterations in the intraocular capillary pressure. He was sure that Priestley Smith's predisposing causes were of great importance. Mr G W HARTY (New Zealand) spoke on Koeppe's theory of pigment migration. He also referred to cases with increasing pallor of the disc after operative relief of the intraocular tension. Dr PARAKORE (Rugby) criticized the physiological facts given by the opener, especially with regard to alteration in ocular pressure being caused by a difference in osmotic pressure of the protein colloid content of the plasma and the aqueous. Oedema of the vitreous strongly appealed to him as a cause of glaucoma. Mr CYRIL WALKER (Bristol) asked for an explanation of the incidence of unilateral glaucoma, he suggested that it pointed to a local anatomical condition. Lieutenant-Colonel A E LISTER (Bristol) described the case of a woman said to have glaucoma. No change was

apparent and the eye was normal in tension to the Schiotz tonometer. The patient said that sewing produced attacks. The next day she sewed for three hours, and he then found her tension was 60 mm of mercury with the Schiotz tonometer. Trephining relieved her symptoms, but two years later the other eye became affected. He thought that the accommodation and convergence were here factors in an eye predisposed to glaucoma. He had noticed how commonly microphthalmic eyes became glaucomatous, pointing to an anatomical basis he had seen the condition in a young patient with a small coloboma of the iris. In reply to Mr Spencer (Baghdad) he said he had not found glaucoma common in trachomatous patients.

In reply, Mr DUKE-ELDEN doubted the accuracy of comparing the eye to a closed box. Fluid could be expressed by massage. He could not agree that the tension in eye and cranium were the same, the former averaged 20 mm of mercury, the latter 10 mm. He agreed that the venous pressure in the eye was about 15 mm of mercury above the intraocular pressure. The large size of the ciliary body was necessary for dialysis, as a large number of capillaries were needful. He agreed that some change in the pectinate ligament was often a determining cause in glaucoma.

SECTION OF DISEASES OF CHILDREN

Thursday, July 26th

CHRONIC NEPHRITIS IN CHILDHOOD

Dr J C SPENCE (Newcastle), in opening the discussion, said that there were no forms of chronic nephritis peculiar to childhood, and it was with the clinical features of the disease as it occurred in children that he proposed to deal. Three main groups could conveniently be considered: chronic interstitial nephritis, chronic parenchymatous nephritis, including nephrosis, and chronic ascending pyelonephritis. The last, although not a primary disease of the kidney, was of importance, since the renal function might be impaired as in chronic interstitial nephritis. Two other conditions were not included, chronic haemorrhagic nephritis and Heubner's "paedo-nephritis," in which children showed no other sign but albuminuria and anaemia; this was probably not a distinct entity. Chronic interstitial nephritis was at one time considered a great rarity, and for some time attracted little attention until in 1911 various workers described the association of the disease with chronic bony changes and dwarfism. There appeared to be three clinical types of the condition, but considered as a group the symptoms were thirst, polyuria, anaemia, and arrested development. Sometimes uraemia was the first sign of the disease. In a minority of cases a history of acute nephritis or a preceding illness of prolonged sepsis was obtained. The patients had coarse, dry, pigmented skins, and were liable to recurrent attacks of uraemic vomiting and headache. There was no mental defect, indeed precociousness was a common feature. Bony changes were characteristic, fractures were common, and the gait was slow and uncertain. Polyuria was a prominent symptom, and the amount of albumin passed was very variable, sometimes being very slight and overlooked. Retinitis occurred in those cases with high blood pressure. Renal function tests showed a great loss of function. All cases of chronic interstitial nephritis appeared to fall into three types. One, called the primary renal type without a history of acute nephritis or preceding sepsis, began insidiously, and cases were often first seen on account of dwarfism or bony lesions. The blood pressure remained normal in this type, and a terminal uraemia with muscular twitchings, vomiting, and coma occurred. The second group comprised a primary renal type with a history of acute glomerular nephritis or prolonged sepsis. Here the blood pressure was raised with cardiac hypertrophy, albuminuria, red cells in the urine, and azotaemia. The third group consisted of cases of primary arterio-sclerosis with secondary contraction of the kidney. Such cases, although rare in childhood, did occur, and Dr Spence quoted one of his own: a child of 10 with a blood pressure of 220 mm systolic. The renal function tests were normal, but so-called uraemic symptoms occurred, such as transient amaurosis and monoplegia of the left arm, which in the presence of albuminuria and retinitis were regarded as

uraemic, although more likely to be the result of a cerebral vascular disturbance. With regard to the aetiology of chronic interstitial nephritis, nothing positive was known about the renal dwarfism cases, although an intrauterine origin was suggested. In the second type sepsis appeared to be the cause, and in the third type the cause of the preceding arterio-sclerosis was unknown. Bony changes in chronic interstitial nephritis which had existed for some years appeared to be the result of a metabolic disturbance, but they did not yield to the usual antirachitic remedies. Tetany did occur, but was not common, except in a latent form. The bony changes and the tetany were associated with a disturbance of the calcium-phosphorus ratio, and it was probable that the parathyroids were concerned with this. In all the cases of chronic interstitial nephritis with normal or low blood pressure retinitis was absent, and Dr Spence concluded that when it occurred retinitis was a manifestation of hypertension or vascular disease. There was little to be done in the treatment of chronic interstitial nephritis. Turning next to the chronic parenchymatous form or nephrosis, Dr Spence said that this was the commonest form in children. The terms used to describe the condition really mattered very little; the word "nephrosis" indicated a degeneration rather than an inflammation, and suggested a general disorder in which the kidneys were involved. Clinically, the disease was well recognized, but the only evidence that the condition was due to disorder of the kidneys was the albuminuria and the casts in the urine. With regard to the diagnosis, the problem had to be faced of whether red blood cells must be absent from the urine and the blood urea necessarily normal as was supposed to be essential in the classical uncomplicated case. In treatment the first essential was to find the local infection, said to be nearly always a staphylococcal one, often in the paranasal sinuses, and remove it. Large doses of alkalis should be tried in obstinate cases, but it was difficult to assess the value of any form of treatment owing to the fluctuations of the disease and the fact that spontaneous cure might take place. A high protein diet was useful, and decapsulation of the kidneys useless, the patient must be guarded against intercurrent infections. The prognosis was uncertain, especially in prolonged cases. Dealing lastly with chronic ascending pyelonephritis, Dr Spence referred to those cases of pyelitis which became chronic and in which permanent ill health resulted. The kidneys went into a condition of azotaemic nephritis, ending in uraemia, and in prolonged cases the children became dwarfed. In such cases the possibility of imperfect drainage of the urinary tract due, for example, to a valvular obstruction in the posterior urethra, ought to be borne in mind so that surgical intervention was not delayed.

Dr NORMAN CARON (Liverpool) thanked Dr Spence for his masterly introduction of a very difficult subject. In his own experience most cases of nephritis were not pure examples of any particular variety, they were due, apparently, to diffuse lesions affecting all the component parts of the kidney. He had found the so-called renal efficiency tests of little practical value in "medical" diseases of the kidney in children, and he felt that there was a real danger of allowing these tests to assume too important a place in assessing the pathology and prognosis in any given patient, though it was obviously proper that they should be used whenever possible in order to try to learn more about their significance. Dr Capan thought that in any classification of chronic nephritis a place should be found for chronic haemorrhagic (glomerular) nephritis, which, in his experience, both hospital and private, was more common than chronic parenchymatous nephritis. He did not think that the apical could justifiably exclude this type of case because it happened to be a recurrence of attacks of slight glomerular nephritis. The speaker contended that most of the cases of chronic nephritis showed acute exacerbations from time to time and that one of the most important items of treatment was to prevent in so far as possible, these recurrences. Removal of mastoid, tonsillar, and dental sepsis in cases of chronic glomerular nephritis was a most valuable form of treatment. In regard to renal decapsulation for chronic parenchymatous nephritis, Dr Capon reported a case in which he had been able to

examine the kidney and its surrounding tissues three months after this operation had been performed. There were only very slight traces of a new capsule, and prolonged microscopic search for new blood vessels passing from the perinephric tissues to the kidney was unsuccessful. Finally Dr Capan asked whether any member had seen cases of orthostatic albuminuria which eventually developed rheumatism. This seemed to him to be a definite though uncommon form of onset of rheumatism.

Dr L. G. PARSONS (Birmingham) agreed that the uraemia occurring in the primary renal type of chronic interstitial nephritis was a true uraemia. He could not remember seeing retinitis in this condition, but primary optic atrophy occurred associated with a special type of bone deformity and a skull resembling Paget's disease in appearance. He emphasized that parathyroid should not be given in this condition, and he pointed out that phosphates, so frequently given in an attempt to alkalinize the urine, were very liable to precipitate an attack of tetany. Chvostek's sign could be elicited in so many conditions that he did not find it of much use.

Dr R. HUTCHINSON said that classification presented a real difficulty, and chronic types of nephritis tended to be mixed, with diffuse changes. It was unusual to find pure types at the bedside. He asked whether we were justified in regarding chronic nephritis as the primary renal type as primarily a disease of the kidney at all. In view of the bone changes it might just as well be looked upon as a variety of rickets. The metabolic disorder present made up a syndrome which included nephritis and bone changes. With regard to ascending pyelonephritis cases had been described as due to a valve in the posterior urethra, and he believed that the condition was not necessarily a pyelitis, but more like the "prastatic" kidney of old men. He asked what was the cause of high blood pressure in chronic nephritis. It was found in one case and not in another. He agreed that the renal function tests were of little help clinically as to the state of the kidney or as to prognosis. He emphasized the importance of casts in the urine in such cases. He could not believe that chronic staphylococcal infection was important in the production of chronic parenchymatous nephritis, but in the glomerular type a focus of infection was frequently present. In oedematous cases tapping was of very great value, and spontaneous diuresis often followed.

Dr J. W. SCOTT (Nottingham) spoke of the arterio-sclerotic type of nephritis in children. He described two cases of this variety with marked retinal changes, normal blood urea and a history of haematuria at the onset. He believed that such cases began as an acute haemorrhagic nephritis. He thought that all chronic nephritis had its origin in slight passing attacks of acute disease. In a large ear, nose, and throat department transient haematuria was of frequent occurrence. In parenchymatous nephritis catarrhal infections—bronchitis, for example—were common. He described a case of parenchymatous nephritis with ascites without any albuminuria. He thought that the onset of vomiting was a bad prognostic sign in nephritis.

Dr C. PAGET LARAGE (Manchester) discussed various points. He thought Chvostek's sign did represent a real abnormality. With regard to Edebohl's operation, he knew of one case in which it was very successful. He was impressed with the septic origin of many cases of chronic nephritis, and rheumatic nephritis would quite well fit in with this. As regarded feeding he held that much of the dieting in nephritis was an the wrong lines, and children were kept from recovering because of too low a diet.

Dr D. T. DAVIES (Cardiff) dealt with uraemia as seen in childhood, pointing out that many chronic conditions of the kidney in children only presented themselves clinically when they had arrived at a state of renal failure. Uraemia it was commonly agreed, was accompanied by nitrogen retention, but some observers denied this, largely because, Dr Davies believed, they had studied the syndrome in adults when it was complicated by vascular changes. The uraemia of childhood had much in common with the "mechanical" uraemia of adults. The most obvious and persistent sign in these cases was vomiting, muscular twitchings and coma followed. Even when very ill these children maintained an alert mental condition. The blood pressure was not raised, and absence of eye signs was the

rule. The urine was pale, often for a time free from albumin, and of low specific gravity. The blood contained very remarkably large quantities of urea, as high as 300 mg per cent might be present, and yet the child complained of very little except for attacks of vomiting. The vomiting led to a loss of hydrochloric acid, meaning a retention of alkali, and this might help to buffer the already retained acid in the shape of acid phosphate. The vomiting attained another purpose, for it helped to get rid of waste products, and very large quantities of urea were sometimes contained in the vomit. Dr Davies quoted a case of a girl, aged 13, with a blood urea of 530 mg per cent and whose vomit yielded 700 mg per cent of urea. He agreed that infection did not seem to be common as a factor in producing "chronic interstitial nephritis." Some cases were remarkably free from symptoms until anaemia terminated the picture. One case, a boy of 15, who had been working in a mine, had only one month's history of headache and vomiting. He was admitted to hospital and died after one day, with a blood urea of 890 mg per cent, non-protein nitrogen 650 mg per cent, and chlorides 231 mg per cent. His blood pressure was only 80 mm systolic. At the necropsy the kidneys showed foetal lobulation and were small in size. In conclusion Dr Davies referred to the question of the undetermined nitrogen in the blood.

Dr A. MONCRIEFF said that in the etiology of chronic nephritis two main factors had to be kept in mind. The infective origin of many cases was emphasized, but others had a vascular origin, as, for example, the acute nephritis following a chill, for which Volhard offered an ingenious explanation. It was obvious that cases of chronic nephritis arising from a primary vascular lesion of the kidney were less amenable to treatment than the "infective" cases. Infection appeared to cause kidney damage in two ways: streptococcal emboli might affect the glomeruli, while toxins would damage the tubules, so that while a hard and fast distinction was impossible, yet the different types of chronic nephritis might be explained on these lines. At the present day missed scarlet fever seemed to be becoming a more important factor in otherwise unexplained cases of chronic nephritis. With regard to diet in chronic nephritis Dr Moncrieff emphasized that Epstein's diet was "low fat" as well as "high protein." This was often lost sight of and might explain the failure of such a diet in cases with oedema, if the fat were not kept low.

The President, Dr A. HOWELL (Cardiff), described a case of chronic interstitial nephritis of the primary renal type without any history of nephritis, which he had had recently under his care. The child had been sent to hospital for orthopaedic treatment for "knock-knees." She had not walked until the age of 5, and for a long time had been subject to attacks of vomiting lasting four or five days. On admission there was definite evidence of rickety changes in the bones, the child was below height and weight for her age, and she looked pale and ill. Her blood pressure was 80 mm, and the blood urea 534 mg per cent. She became comatose and died quietly. The kidneys were extremely small at necropsy, without any changes in the renal artery. This child had been ill for thirteen years, and Dr Howell emphasized the need for recognizing such cases. With regard to streptococcal infections and nephritis he thought all such cases should be treated as early as possible, much as rheumatic children were treated, for teeth, tonsils, naso-pharynx, etc., if these were infected.

Dr H. GAINSBOROUGH said that he was very struck with the extreme diversity of renal symptomatology. It was very difficult to correlate renal damage with symptoms or groups of symptoms. He disliked the term "nephrosis," and thought the disease identical with chronic parenchymatous nephritis in adults. It was frequently complicated by glomerular disease producing much difficulty, and Dr Gainsborough believed that it really began as glomerular disease, going on to chronic parenchymatous change. Albuminuria was evidence of glomerular change, and in experimental nephritis large doses of poisons would always produce glomerular changes. He did not agree that there was any more connexion between cholesterol and fat than between cholesterol and the proteins in the plasma, and with regard to diet in cases of parenchymatous nephritis

he had found a fat-free diet useless. He thought decapsulation an unsatisfactory procedure, but in any case the prognosis in the condition was very uncertain.

Dr J. C. SREXCE, in reply, said that the scheme of classification he had put forward was only an attempt to help in the understanding of the disease. He thought that everyone would agree that there was a disease in which, without a history of preceding acute nephritis, contracted kidneys occurred associated with bony changes and dwarfism, but the type of kidney found at autopsy was rather a puzzle pathologically. He mentioned a case in which bony changes had occurred after ascending pyelonephritis had damaged the kidney. He agreed that casts should always be looked for, but there was a danger of forgetting the red blood cells. He thought urea had been dismissed too lightly as a cause of true uraemia.

Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

A HAIR SLIDE IN THE BRONCHUS

THE removal of a foreign body from the lung with the aid of the bronchoscope is not an uncommon occurrence, and there would be no need to report this case if it did not present unusual features of interest both clinical and anatomical. The foreign body was a hair slide 2 inches long and 9/32 inch in width, made of tortoiseshell with a metal clasp.

The patient was a girl 3 years old. On February 13th, at 8.30 a.m. she was sucking the hair slide and suddenly became asphyxiated with stridulous breathing. She was immediately taken to the Birkenhead General Hospital where the house-surgeon thought he felt with the finger something hard in the back of

the throat. The bronchoscope was promptly passed but without discovering the foreign body. I first saw the child in the evening twelve hours after the accident. The breathing had then become easier and the stridor had disappeared but the child was ill, the respirations being 32, the temperature 100° and the pulse 156. Very little air was entering the right lower lobe and there were signs of bronchitis from which the child was said to have been suffering at the time of the accident. The radiograph showed the intruder in the right bronchus. Chloroform preceded by atropine was administered and the bronchoscope again passed. The 7 mm tube was held up at the subglottic region and had to be withdrawn and replaced by the 5 mm bronchoscope. No foreign body could be seen probably owing to the almost incessant coughing and mucopurulent expectoration. After an interval of two days a further effort was made to remove the foreign body through the 5 mm bronchoscope but was again frustrated by the cough and expectoration. Since the child was now very ill and quite unable to stand any further attempt at removal I performed a low tracheotomy and, passing the 7 mm.

tube through the tracheal opening, succeeded in removing the foreign body. It was somewhat fixed *in situ* so that a little traction was necessary to dislodge it which I attribute to the inflammatory swelling of the mucous membrane and the consequent narrowing of the bronchial lumen.

The child continued very ill for another ten days with septile broncho-pneumonia but eventually made a complete recovery. The tracheotomy tube was discontinued to a fortnight.

The principal points of interest in the case are

1 In a child aged 3 the 7 mm bronchoscope will not pass the subglottic region

2 The presence of bronchitis makes bronchoscopy difficult, especially when the 5 mm tube is used

3 The tracheal opening allowed the larger size 7 mm bronchoscope to be used and afforded an easy vent for the large quantity of pus which was subsequently expectorated

4 The foreign body defines the exact position of the main bronchial stem on the right side. It shows that in a child 3 years old the trachea divides at the level of the third dorsal spine, one vertebra higher than in an adult, that the right bronchus is only at a slight angle with the midline, that the bronchus continues outwards, downwards, and backwards in a straight line for at least two inches from the tracheal bifurcation, and without any marked narrowing of its lumen.

The radiograph indicates that a foreign body small enough to enter the right bronchus might easily, by gravity or suction, pass deeply into the substance of the lower lobe.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION ANNUAL GENERAL MEETING

THE eighty-seventh annual meeting of the Royal Medico-Psychological Association was held on July 11th, 12th, and 13th at the West Riding Mental Hospital, Wakefield, Yorkshire, under the presidency of Professor J SHAW BOLTON, M.D.

The following representatives of foreign psychiatric societies were present: Dr E. N. Brush (U.S.A.), Professor Wimmer (Denmark), and Dr Hans Evensen (Norway). At the business meeting Dr C. Hubert Bond, Dr Eugen Bleuler (Zurich), and the Right Hon. Hugh Macmillan, K.C., were elected honorary members. Dr Malcolm A. Bliss (St. Louis, U.S.A.), Dr C. O. Ariens Kappers (Amsterdam), Dr George H. Kirby (New York), Dr Giacomo Pighioli (Reggio Emilia, Italy), and Professor August Wimmer (University of Copenhagen) were elected corresponding members. The appointment of Professor C. E. Spearman as Maudsley lecturer for 1929 was announced. The Gaskell Gold Medal and Prize for 1927 was presented to Dr Elizabeth Casson, and those for 1928 were awarded to Dr I. R. Martio. It was intimated that H.R.H. Princess Mary (Viscountess Lascelles) had signified her willingness to accept the association's nursing medal in gold and the honorary certificate for mental nursing.

Professor J SHAW BOLTON took for the subject of his presidential address "The evolution of a mental hospital Wakefield, 1818-1928." He said it was nineteen years since the West Riding Mental Hospital provided a president of the association, in the person of Dr Bevan Lewis. Wakefield could claim to be a mother of asylums, and it had reached a distinction accorded to but few. The first Workfield asylum was opened in 1818, the second was added in 1853 and the third added was the modern building known as "The Acute." Sir William Ellis was the first director, and later went to Hanwell. The speaker quoted at length from regulations—some of which showed much foresight, while others would now be regarded as humorous. The director was the supreme officer, and he also acted as apothecary, surgeon, steward, and treasurer. At the opening two visiting surgeons and two visiting physicians were appointed, but in 1821, probably on account of the confusion resulting from dual control, the visiting magistrates much increased the powers of the director and diminished those of the physicians. In the minutes of July, 1857, there appeared a reference to Dr Henry Maudsley, who was then on the Wakefield staff, while one of the earliest workers in the Wakefield laboratory was Sir James Crichton Browne.

That gentleman not only fostered research, but did his best, by lectures, etc., to promote a general medical interest in the work and administration of the hospital. Resident clinical assistants (unpaid) had been appointed from early times. Sir David Ferrier's connexion with Wakefield Mental Hospital was well known.

The president proceeded to sketch the various additions to the buildings, and the improvements in treatment and administration which were effected in the course of the years, discussing at some length the question of punishment of patients for gross misdemeanours. Since he took office mechanical restraint and punishment had ceased, both in fact and in name, and that if he had the authority he would render restraint of all kinds, not only illegal, but criminal, on the part of any one who ordered it without having first experienced its effects on his own person. He drew attention to the close association with the University of Leeds, and the advantages accruing therefrom, making particular reference to the establishment of the pioneer diploma in psychological medicine.

Sir ROBERT ARMSTRONG-JONES proposed, and Dr J BRANDER (Boxley) seconded, a cordial vote of thanks to the president for his address, which was accorded by acclamation.

On July 12th Dr M. J. McGRATH (Wakefield) opened the scientific proceedings by reading a paper entitled "A description of the steps taken in a mental hospital to prevent the spread of dysentery and allied infectious diseases." In connection with this subject, the president read a postponed extract from his presidential address, describing the seriousness of some of the epidemics of dysentery which at various times in the past had afflicted the inmates. The precautions now taken to detect and, when found, isolate and thoroughly treat a case of bad diarrhoea or dysentery were given in detail. Dr McGRATH said it was essential to have isolation wards for new admissions and infected cases. Infection of inmates not only occurred through infected cases transferred from other places, but from new members of the staff. Hence every fresh patient and each new member of the staff was submitted to a thorough routine physical examination for infections. Of 467 probationers, 83 had to be rejected as a result of this examination. The organization of this work had been prolific of good results. It was insisted that an institution entirely free of dysentery was peculiarly liable to infection from without, particularly if a foreign strain were brought in. Investigations led to the conclusion that periodic temporary immunization of institutions in this respect was constantly occurring.

Mr A. L. HOWDEN (Wakefield) read a paper and demonstrated the bacteriological methods employed at the hospital in regard to the detection of dysentery and allied infectious diseases.

Dr J. R. LORD (Horton) spoke in praise of the modern skilled laboratory assistant, and said this was the first occasion he recollected on which one had read a paper before the association. He congratulated Mr Howden.

Dr F. A. PICKWORTH (Birmingham) said that at the Birmingham Mental Hospitals, in addition to isolating those who showed a positive Widal reaction, they treated likewise all who had had contact or relation with typhoid patients, or who showed infective organisms in the faeces.

Dr F. R. P. TAYLOR (Hellingly) said that at Hellingly dysentery cases came among the patients transferred from other hospitals, and it was not until regular bacteriological examinations were made the rule that real good ensued, though isolation had always been carefully enforced.

Professor J. W. McLEOD (Leeds University) expressed his surprise that Shiga infection epidemics did not occur in mental hospitals, and dealt with a number of points in technique. Dr C. HUBERT BOND said these communications must have brought home to everyone the absolute necessity of mental hospitals possessing a laboratory. He praised the work of Mr Howden. Dr J. I. RUSSELL (York) referred to the different types of dysentery and the difficulties of differentiation.

Dr L. WYNN-JONES (lecturer in psychology, Leeds University) read a paper on an investigation into the significance of perseveration, saying that there were five kinds of perseveration: sensory, motor, ideational,

emotional, and conative. He dealt only with the first three. The PRESIDENT and Dr. LORD discussed the paper.

Professor B. A. McSWINEY (Leeds University) contributed a paper on physiology in relation to psychological medicine. He stated that the paucity of information on cerebral function in the textbooks was due to absence of methods available to investigate the normal activity of the higher nerve centres. The explanations advanced often took no account of the function of the lower nervous system in bringing about the requisite co-ordination and relationship between the different organs of the body. If knowledge of the physiological factors controlling mental activity were to advance, the physiologist must continue to make measurements on structures which he was able to control, and carry out investigations in which he was able to isolate the disturbing factors. He illustrated his thesis by a number of examples, many of which were illuminated by the work of Sherrington and others.

Dr. IAN SUTTIE (Fife) read a remarkable paper on neurotic superstructures in certain psychoses, which consisted mainly of an elaborate justification of the early treatment by psycho-analysis, and illustrated well the degree of concentration and patience required successfully to pursue the method.

The PRESIDENT followed with a lantern demonstration of the stages the egg passed through in the germination of the chick, illustrating clearly the final mechanism which resulted in the emergence of the chick into the outer world.

On Friday morning Dr. K. C. PADDLE (Wakefield) gave a review of blood pressure in the insane, based upon the careful examination of 920 male patients, care being taken not to excite them before or at the time of the examination. The cases were divided into seven groups. Summarizing his results, Dr. Paddle said that in melancholia 51 per cent of cases had a subnormal blood pressure, in mania 51 per cent had a subnormal pressure, in epilepsy 70 per cent had a subnormal pressure. The average blood pressure in the insane varied according to the age. The majority of insane epileptics had a constantly low pressure, independently of the frequency of the fits or the kind of epilepsy. The blood pressure of normally minded epileptics might be raised by arterio-sclerosis or chronic Bright's disease.

Dr. F. A. PICKWORTH (Birmingham) contributed a paper entitled "Variation in the agglutinin formation in mental hospital patients and its probable relation to focal sepsis." His main purpose was a consideration of how the system might be invaded by organisms which demanded a considerable production of antibodies to effect their destruction and removal from the system. The organisms normally present in the jejunum evidently migrated to higher levels, as shown by examination of over 200 cases. The interrelation between focal sepsis and the variation in agglutinin formation of the insane probably occurred through the medium of a high intestinal sepsis caused by infection with paratyphoid or food-poisoning organisms.

Dr. J. F. SLYTH (Wakefield) read a paper on the relation of the *Spirochaeta pallida* to the histological changes in dementia paralytica. He said that spirochaetes were found in 75 per cent of the cases, occurring most frequently in cases which ran a stormy course. The speaker gave an exhaustive treatise on the mechanism of the disease, concluding that the most that could be hoped for under treatment was an arrest of the damaging process to the cortex. The number of cases examined was 52.

Dr. JOHN BRANDER (Bexley) discussed in a paper general paralysis of the insane as a clinical and pathological entity.

Professor W. H. MAXWELL TELLING (Leeds University) read an interesting paper on the value of psychical research to the physician, in which he declared that he had received great benefit from a study of psychic phenomena. He proceeded to review the present state of knowledge and the tendency in the profession concerning this subject. His own attitude was very sympathetic towards such subjects as telepathy.

The concluding item was a demonstration by the PRESIDENT of cases of sense deprivation and cases showing the primary importance of the aural centres in the cortex cerebri.

Reviews.

LOUIS BROcq'S LECTURES

It is now forty seven years since Dr. Louis Brocq became physician to the Hôpital St. Louis, the great dermatological centre of Paris, and although it is several years since he ceased to be an active member of the staff his vigour remains unabated and his output undiminished. In 1924 he published a large volume of clinical lectures, and this is now followed by a second of equal size and of equal interest. This volume contains fifty eight lectures, and of these no fewer than thirty seven are here published for the first time. The remainder are reprinted from various sources, but all are arranged so as to constitute a consecutive series, or rather five separate series, for the whole volume is composed of five sections with a single preface. One section, entitled "*Généralités*," like the preface, largely concerns itself with the philosophy of dermatology, laying down the principles which have guided the writer and incidentally pointing out the errors into which others have fallen. There is a section on the general therapeutics of skin diseases which, while dealing largely with questions of principle, is also full of useful practical hints and can be commended to the practitioner. The same can be said of the next section, which, entitled simply "*Panorama*," is so exhaustive that it really constitutes a fairly complete textbook of external dermatological therapeutics. It includes also a chapter on the treatment of skin diseases as carried out at spas. Those who desire to send their patients to drink the waters of health in these resorts will find much useful information here, at all events regarding French watering places. Brocq maintains a very sane and detached attitude towards their merits, and quotes with approval the dictum of some former medical philosopher—"the physician makes the spa." The author does not belong to the hair-splitting school of dermatologists, he preaches a doctrine remarkable for its breadth of vision rather than for anything else. Almost the only definite cutaneous diseases (*entités morbides vraies*) the existence of which he allows are those relatively few conditions whose etiology, whether bacterial, parasitic, or chemical, is clearly established. The remainder he includes under the single heading of cutaneous reactions, and his constant endeavour is not to split them up into smaller and smaller groups, but to recognize the connexions (*faits de passage*) between the various syndromes which we are bound to accept in order to obtain some clarity of description, and to which we commonly affix a label indicating their clinical characteristics. The significance of these labels is generally understood among dermatologists, but Brocq warns us against thinking that the choice of the appropriate label in any particular case is in any way equivalent to making a real diagnosis. Nevertheless, there are certain clinical groupings, now generally recognized among dermatologists, which this author has largely helped to establish, among these are the various forms of parapsoriasis and the doctrine of lichenification (a term invented by himself). In the present volume valuable chapters are to be found dealing with these, both from the historic and clinical aspects, and the author indicates that in certain details his own views have undergone some change in the course of years. Many other topics are touched upon in these pages—including a series of new lectures on various forms of hyperkeratosis, and furrows and fissures in the tongue—and, like most other dermatologists, Brocq has something to say on the absorbing problem of alopecia areata. On all these subjects he is interesting and stimulating, we may not agree with all the doctrines advanced, but at all events thought is provoked. His powers of clinical observation and description are very fine, and, like most French physicians, he has the ability to clothe his ideas in eloquent and forcible language. As might be expected, he is not a strong pathologist, when he was in his prime pathology was in its infancy, but he is quite able to appreciate the great importance of modern pathological advances.

This is a volume of considerable length but all who are interested in diseases of the skin should read it from start to finish. The author is the "grand old man" of dermatology.

CHEMOTHERAPY

In producing *The Chemistry of Chemotherapy* Dr MALCOLM DYSON has accomplished a very heavy task in a very satisfactory manner. The book contains a valuable account of a large number of substances and its arrangement is excellent. Many hundreds of chemical compounds are dealt with, they are classified, as far as may be, on a chemical basis, and the author has adopted the helpful scheme of inserting the structural formula of each substance, as it is mentioned, in the text. By this means the reader can grasp fairly easily the relationship of one compound to the next.

It is, perhaps, legitimate to criticize the author in one respect. He has very properly, omitted all irrelevant details about the biological action of the materials under discussion, but he has perhaps paid rather too little attention to biological considerations in general. For instance, the phrase "the most powerful of metabolic enzymes" (p. 20) seems to suggest a certain confusion of thought. Since no enzyme has yet been isolated in a pure state, we have no absolute measure of potency, but the evidence suggests that enzyme action on a suitable substrate proceeds as rapidly and completely as conditions allow, not that there are, for example, gradations of potency among enzymes as there are among the oxidizing agents of the laboratory. Again, in discussing certain substances, particularly the quaternary ammonium bases, the suggestion is made that the substances act upon, and paralyze, motor nerve endings because only at the nerve ending is the axis cylinder unprotected by myelin sheath. But the substances, after injection, must have ample opportunity of coming into contact with, and acting upon, non-medullated nervous tissue. Yet effects upon unstriated muscle, glands, and the circulatory apparatus are in no way prominent features of their activity.

One cannot help a feeling of depression—for which the author is in no way responsible—after reading the book. Chemotherapy is a subject of the greatest importance to medicine, it has scored several striking successes, and yet there is little to suggest that these successes have been more than lucky shots. Apart from the work of Crum Brown and Fraser in 1868, no general principles seem to have emerged, yet until general principles have been laid down there is no guarantee that any given piece of work is really on the right lines. It seems almost pertinent to inquire whether some of the time and resources spent on chemotherapeutic research might not more profitably be diverted to the study of the chemical and physical mechanisms of the cell, upon which for the most part our drugs must act, and about which we still know so little. In the last few paragraphs of the book the author himself rejects the possibility that physiological activity can ever really be correlated with the "gross details of chemical structure", he believes that ultimately such correlation may be attained with regard to physiological activity and the energy relations of the ultimate parts of the molecule—the electrons and protons. If this be so, obviously the preliminary step must be to gain a knowledge of the intimate mechanisms of the cell.

TESTS OF FUNCTION

A NUMBER of papers on function tests of internal organs, which originally appeared in the *Klinische Wochenschrift* have been collected in a small volume² apparently intended as a summary of tests of practical diagnostic value for the guidance of general practitioners, investigations involving the use of x-rays are omitted. That the writers of the various chapters are not all equally successful in attaining this object is no doubt partly due to the complexity of the subjects and to the fact that numerous function tests

The Chemistry of Chemotherapy. By G. Malcolm Dyson. Ph.D. London: E. Benn Ltd. 1928. (Cr. 4to pp. vii + 272, 6 figures, 32s. 6d. net.)

² *Funktionsprüfung innerer Organe*. By various authors. Second edition. Berlin: J. Springer. 1927. (5½ x 8½ pp. 150 R.M. 60.)

recently advocated are still on trial. One of the best chapters is that on the stomach by Professor Grote. In discussing gastric secretion and "emptying time," he describes certain modifications and rough tests which are likely to be useful to those who have only very limited laboratory facilities at their disposal. The chapter on the electro-cardiogram gives a concise account of this method of diagnosing the origin of the commoner cardiac irregularities. In the chapter on the kidneys the artificiality of many renal function tests—for example, those involving the injection of dye stuffs—is deprecated, and the value of water excretion tests and the simpler concentration tests is once again emphasized though stress is laid on extra-renal factors, such as oedema, which may interfere with so-called renal function tests. The chapter on intestinal function enumerates various methods of examining specimens from the small intestine, but fails to describe how these are to be obtained. Simplifications of various tests in common use are, however, given—for example, for occult blood in the stools by tablets containing benzidine and barium peroxide. Though the time taken by a dose of charcoal to pass through the intestinal tract is generally recognized as a useful measure of possible intestinal stasis when x-rays are not available, this method is not even mentioned, nor is any other means of estimating the motor functions of the intestine given. Other chapters deal with the heart, liver, pancreas, and endocrine organs, and a concluding chapter of much interest is devoted to the pharmacological tests of the vegetative nervous system. The volume suffers from some of the defects, such as overlapping of material, which are common when independent articles are re-published together in one book: thus there are three separate accounts of Loewi's conjunctival adrenaline test in itself of theoretical rather than practical interest. A more serious defect is the omission of an index to the numerous tests described. Considering its size, however, the book contains much of practical value, and should prove useful to those who are too busy to study larger treatises on the subjects under review.

SUICIDE

THE textbooks issued by American universities, whether the series be medical, sociological, or literary, tend to be heavy in both the physical and the intellectual sense. A study on *Suicide*,³ by Dr RUTH SHONLE CAVAN, issued by the University of Chicago Press, is no exception. In this book, as in others of a like nature whatever be the particular subject of study, a great many facts are brought together, a large number of graphs and tables are constructed, and a considerable number of individual cases are recorded and analysed. The results are not always commensurate with the labour involved or with the show of research displayed, nor are they in this instance. The work was perhaps worth doing in so far as it brings within the compass of one volume certain facts and statistics which readers with a particular purpose in view may find it convenient to have so collected. Some conclusions, mainly negative, are arrived at, and these may have some importance but no very valuable conclusions or even suggestions emerge which may not already be regarded as the common-places of sociological or psychological knowledge concerning the relation of the individual to the group and the relative importance of custom and public opinion as compared with individual motives and temperament.

In some societies suicide is or has been, in the nature of a social institution—*sente hana hani* suicide of the sick or aged among the Eskimos are examples. Certain scales of values are held by the entire group as part of the group tradition: they are accepted implicitly by each member, so that individuals willingly give up their lives to maintain these values. The modern custom approved as an act of heroism, whereby a captain goes down with his ship, is of the same nature. On the other hand, in stabilized and relatively small societies, or under the influence of certain philosophies or religions, peculiarly Christianity, group loyalty condemns all suicide as antisocial or sinful. On either of these positions marked social disturbances

Suicide. By Ruth Shonle Cavan, Ph.D. Chicago: University of Chicago Press. 1928. (5½ x 8 pp. xxvii + 359, 6 figures, 15s. net.)

(whether periods of social change, sudden and widespread epidemics of disease, or the contact of different cultural groups) have a disruptive effect. The decline of Greece and of Rome, the Black Death, the Renaissance, may be taken as examples. Habit and custom become inadequate to effect personal adjustment, and the individual is left, with lessened social support, to face those crises which threaten the uncertain equilibrium between his desires and the possibilities of their fulfilment. Social disorganization removes the prop which prevents personal disorganization. The general line of inquiry in Dr Cavan's study is, first, as to evidence of any general characteristics influencing large groups or communities, and second, an attempt at some analysis of the factors which produce personal disorganization.

The most interesting conclusions with regard to the former are that there is no statistical or other support for the idea that climatic conditions have any real influence over the prevalence of suicide, or for the statement that there are any underlying national or even racial differences in this regard, and that the undoubted preponderance of suicide in men as compared with women, in older persons rather than younger, and in widowed or divorced persons as compared with the single or normally married, may best be accounted for by the fact that the former class in each case has to meet the crises of life to a much greater extent than the latter. The factors which produce personal disorganization, to such an extent that the natural attempt at adjustment in some form fails and death is therefore sought, are inquired into by an examination of a number of individual cases of suicide or attempted suicide. No specially noteworthy or valuable conclusion or classification seems to emerge, and the suggestion that all those persons who attempt or achieve suicide and who have not previously shown definite signs of insanity must be regarded as normal is scarcely justified. As Professor Ellsworth Fairs says in his introduction to the book, "The readers will learn many interesting things about suicide, but the book will not answer all the questions that might be asked."

NEW GROWTHS OF THE BLADDER

The Pathology, Diagnosis, and Treatment of Neoplasms originating in the Walls of the Urinary Bladder,¹ by the late Mr L R FIFIELD, is the essay for which the Harveian Society awarded to the author the Buckton Browne prize. The final proofs of the book had just been corrected when a street accident deprived the London Hospital of one of its most promising younger surgeons. In Parts I and II the pathology, diagnosis, and treatment of bladder growths are described. Part III gives an account of experimental work undertaken by Mr Fifield on transplantation of the ureter into the bowel. This work was done primarily with the object of determining whether ascending infections following uretero-intestinal anastomosis travelled by way of the lumen or of the lymphatics. Did it occur independently of stricture formation, and what was the relative value of Stiles's and of Coffey's operations in preventing it? The author found that even with correct and careful technique about 60 per cent of cases of oblique transplantation of the ureter into the bowel developed ascending infections. In about 30 per cent of his cases a stricture was found at the lower end of the ureter. Although the formation of a stricture prepared the way for a renal infection, this could occur quite independently of any obstruction, the path of infection being either by the lumen or by the lymphatics. In cats and dogs, whose ureters are thin-walled, infection by the lymphatics could be prevented by painting the ureter above the suture line with rectified spirit, but in man such a prophylactic measure would probably be inadequate. There appeared to be little difference in the relative value of Coffey's and Stiles's operations. In view of the frequency of infection and stricture formation neither of them could be considered perfect. Infection occurred after these operations, either by lymphatic spread or by way of the lumen, as the result of reversed peristalsis and the forcing upwards of

grossly infected urine lying in the intramural ureter. The third part of the work is by far the most interesting, since it contains original observations and suggestions. It is deeply to be regretted that by his sudden death the author's researches on this important subject have been brought to an end.

NOTES ON BOOKS

THAT Dr T DAWTREY DREWITT'S *Romance of the Apothecary's Garden at Chelsea*,² originally published in 1922 (vide *British Medical Journal*, 1922, ii, 1269, and 1924, i, 787), should have passed into a third edition is no surprise to those familiar with the charm of its contents. In the present edition this is enhanced by the admirable setting of the Cambridge University Press, which now publishes in a more attractive form, and with additions, a book which appeals to all lovers not only of the medical, but of other aspects of life in old London.

We take this opportunity of welcoming the fourth edition of Dr HOWARD HUMPHRIS'S little book on *Artificial Sunlight and its Therapeutic Uses*.³ The author was one of the first in this country to provide the medical public with a practical manual of this subject. It is the early bird which catches the worm, and Dr Humphris has had his reward in four editions in four years. In general, the character of the book has not altered, although it has become a little more bulky. Additions have been made in order to bring it up to date, and the author remains as fully an optimist as ever. It is true that he expressly disclaims the ultra-violet rays as a cure-all, but by the time the reader has gone through the list of conditions for which it is recommended he will probably feel that but little scope remains for other methods of therapy. Dr Humphris has an attractive and breezy literary style, and the volume is well printed and bound.

Dr URBAIN has written a practical study of the Bordet Gengou reaction as applied to the diagnosis of infectious maladies,⁴ more especially those common to man and animals. The earlier chapters deal with alexine, emulsions of red cells, haemolytic serums, antigens, and so on. Subsequent chapters deal with such diseases of mammals as can be diagnosed by means of this technique. The volume is critical, and contains many of the author's own observations as well as an extensive bibliography. It is essentially practical, and should be of considerable value to laboratories as a technical work of reference.

PREPARATIONS AND APPLIANCES

AN EXPANDING AIRWAY FOR USE IN SURGICAL OPERATIONS. Dr R. G. KARN, assistant anaesthetist to the Central London Throat, Nose and Ear Hospital, writes: Messrs A. Charles King and Co. have made for me the expanding artificial airway shown in the illustration. It is designed to hold forward the base of the tongue and the epiglottis during the prolonged administration of anaesthetics and is placed in position with the posterior ends in apposition forming an ordinary flattened tube. By means of a small screw the posterior portion is then made to open as shown in the diagram, the lower and anterior portion carrying with it the base of the tongue. Counter pressure, to prevent the airway being pushed out of the mouth when it is opened, is secured by the projecting plate on the upper surface which being inserted behind the upper incisors, limits movement in a forward direction. Provision for edentulous patients is made by two holes, one on each side of the forward opening, wherein tapes can be inserted and tied behind the head.

I have found this airway of the utmost value in long operations on the head and neck where it is essential for the anaesthetist to be out of the way of the surgeon and the necessity for the introduction of endotracheal catheters is thereby avoided in a larger number of cases. In addition the clear airway ensured greatly increases the safety of the patient and the comfort of the nursing staff during the transport of an anaesthetized patient from the operating theatre back to bed as the jaw does not have to be held forward constantly.

It is necessary for the patient to be well under and properly relaxed before the airway can be introduced, otherwise some trauma may occur in introducing it and the tongue if rigid is not gripped and pushed forward. Once in place, however, the airway will be found to be tolerated with a much lighter degree of anaesthesia.

SATURDAY, AUGUST 11TH, 1928

SLEEP AND ITS DISORDERS

THOUGH there is something so simple and natural about sleep the numerous theories that have been advanced to explain it serve to reveal the obscurity in which our knowledge of the fundamental principles of organic behaviour is enveloped. In common with all vital reactions sleep still remains a mystery, but this does not deter us from seeking to discover the conditions which favour its occurrence and those which lead to its disturbance. In the contrasting states of sleeping and waking we observe one striking instance of the rhythm which characterizes all the unconscious biological processes, and since this sleep-waking cycle, whose integrity is essential to the well-being of the individual, is so liable to disturbance under the conditions of modern life, the study of sleep and its disorders has become one of considerable importance to the medical practitioner.

Insomnia is the most common disorder of sleep, and the question arises whether sleeplessness in itself has or has not baneful effects upon the biopsychic organism. Experiments carried out by persons who have deprived themselves of sleep for as long as possible demonstrate that the physical and mental changes following voluntarily induced insomnia are not of a serious kind. We are inclined to think, however, that such experiments have only a remote bearing upon the problem of insomnia in the nervous subject. Sleeplessness in an individual who wishes to sleep, but cannot do so when he tries, is probably more harmful than sleeplessness in one who is able to sleep, but does not wish to do so. In the latter case the subject is tranquil and interested; in the former he is beset with fears and preoccupied with gloomy thoughts. Dr R. D. Gillespie in an interesting article on sleep which appeared at the close of last year,¹ expressed the opinion that the influence of insomnia in the production of mental disorders has been much exaggerated. He states that he has not seen a case in which it could be regarded as anything but a minor factor, and that the *causa causans* lies always behind the sleeplessness. Insomnia must clearly be instigated by some endogenous disturbance, such as physical pain or a state of biomenal tension, but when once established the secondary effects can scarcely be otherwise than harmful, it can at least, as Dr Gillespie observes, aggravate an existing neurosis. In sleep there is increased activity of the autonomic functions. The pupils are contracted, the digestive organs continue to perform their functions, possibly more effectively than in the waking state, if we judge by the spontaneous behaviour of infants and animals after a meal: the blood pressure is reduced and the secretory activity of the skin is increased. Put briefly, the restorative processes of the organism are in full operation. Finally, the form of our mental activity alters

during sleep. It is not that the environment ceases to influence the psychic life. Experiments have shown that sensory stimuli exert a constant influence upon the dream content, but such impressions are mere stimuli, they have no significance as situations and events, as in waking life. The dissociation of thought from motor activity, together with a change in the form of thought, are the essential characteristics of sleep. Sleep is, above all, the resting time of consciousness, it affords a release of biopsychic tension, and permits effortless dream fantasies, unhampered by the cramping influence of external reality, to replace the vigilant and attentive psychic activity which the waking state demands.

Dr Gollan² has pointed out that the effects of nocuous stimuli on the organism, as revealed by the psychogalvanic reflex, favour the philosophic view that pain rather than pleasure is the fundamental fact of life. The response to a nocuous stimulus, associated with displeasurable feeling, is an increase of organic activity, whereas the reaction to a benign stimulus, associated with pleasurable feeling, is one of diminished activity. Pain is thus the conscious symbol of organic activity, while pleasure is the symbol of organic relief from the activity occasioned by a nocuous stimulus. It is thus permissible to inquire whether benign stimuli, with their pleasurable sensory aspects, should not be considered merely as an interruption of the stream of nocuous impulses which spur the organism to activity. We feel that the view here presented is of fundamental importance. There are in our modern civilization many sensitive, highly organized, and conscientious individuals who seldom obtain relief from pain—using this term, of course, in its psychological sense. Such persons are constantly faced with domestic, professional, or financial difficulties which are too often incapable of permanent solution. Briefly, life in such cases involves a chronic state of inner tension, with but short periods of relief and psychic relaxation. From what has been suggested above it would seem that sleep in persons so constituted is essential for their well-being; for in sleep we have the completest possible form of rest. Relatively speaking, the biomenal organism has nothing to do during the hours of sleep: it merely has to be—to remain passively in a state of pleasurable inactivity. Fortunately, in the majority of such cases no serious disturbance of sleep rhythm occurs, but should insomnia supervene there is some likelihood of a nervous breakdown. It is not as if the sleepless subject is able to be passively and indulge in pleasurable fantasies, more common is a state of tension, feelings of apprehension, and obsessing thoughts of anxieties and bothers to be faced on the ensuing day. Nocturnal ruminations on personal difficulties are especially fatiguing since no effective action is possible. When, during the day, these difficulties have to be met face to face, action is possible which leads at least to their temporary solution and in this way the 'nocuous stimulus' is removed, so that pleasure replaces pain, but at night, if sleep refuses to come, no such replacement is possible. Sleeplessness of this kind involves excessive organic activity, hyperfunction of the sympathetic nervous system, and a

¹ Sleep and the Treatment of its Disorders. *Guy's Hospital Gazette* November 1927.

² Croonian Lectures on the Objective Study of Neurosis. *Lancet* 1921, ii pp 115, 215, 265, 373.

lessened capacity to face the problems of the coming day. It is not surprising if symptoms of fatigue develop, and it may even happen sometimes (as Sir Maurice Craig and French and Italian psychiatrists in particular believe) that toxic exhaustive psychoses can develop as a result of a vicious circle of biological events set up by insomnia in certain subjects. Thus insomnia is a symptom which clearly merits the close and thoughtful attention of the medical practitioner. Its causes are infinite in their variety, and in its treatment no fixed rules can be laid down. It need hardly be said, indeed, that we do not treat insomnia, but an individual who cannot sleep.

For clinical purposes Dr Gillespie finds it convenient to classify sleeplessness according to whether it is due to physical disease, external irritation, or psychic disorder. It is the insomnia associated with the milder forms of mental disturbance which presents the greatest difficulties in treatment. In dealing with such a case the practitioner is faced at the outset with the problem as to the advisability or otherwise of prescribing hypnotics. That there is some divergence of opinion on this matter was shown by the prolonged correspondence in this *Journal* last year¹ arising out of a discussion, led by Sir William Willcox, at the Royal Society of Medicine, on the pathological effects of hypnotic drugs of the barbituric acid and sulphonal groups. As a counsel of perfection it might be urged that treatment should be directed to the removal of the endogenous irritant which keeps the biopsychic organism awake when it ought to be asleep. To adopt such a policy would, however, be to depart from clinical realities, because we cannot ascribe a neurosis to an isolated and independent cause, which is capable of being removed like an aching tooth, rather is it the expression of a number of mutually interrelated external and internal factors, associated not only with immediate life situations, but also with temperamental qualities and faulty habits of reaction dating back for many years. In some cases simple psychotherapeutic procedures combined with physical therapy, will suffice to dissipate an anxiety state and to restore the sleep-waking cycle to the normal. In others prolonged treatment is necessary to bring about a readjustment, and meanwhile the continuation of insomnia will tend to aggravate the symptoms. Thus there are many cases in which hypnotics are indicated, and these drugs, wisely prescribed, may not only be curative in their effects by providing the rest which is sorely needed but they may also be instrumental, according to Sir Maurice Craig, in sometimes averting a serious mental breakdown.

In the correspondence referred to above exception was taken by some of the contributors to the taking of drugs of the barbitone series over a long period. It would certainly seem desirable in such a case that the drugs should only be taken under medical supervision, but since they can be obtained from the chemist with comparative ease by anyone who wishes, there is nothing to prevent their misuse by the psychopathic subject. For this reason some clinicians are strongly of the opinion that it is in the public interest to control the prescription and sale of veronal, medinal, luminal, and the rest of the barbitone series. The problem is by no means simple; however, and impressive arguments are advanced both for and against the inclusion of these hypnotics in the official list of dangerous drugs. It is beyond our present purpose to discuss this highly controversial matter; our object here is to

remind readers of the importance of sleep for the preservation of health, and to emphasize the necessity of treating its disturbances seriously and with all possible medical skill.

THE DOSAGE OF DRUGS

In his preface to the new (nineteenth) edition of *The Extra Pharmacopoeia* (reviewed in our issue of July 28th at page 155) Dr W. Harrison Martindale raises an interesting point about the dosage of new drugs. He remarks that in the case of many of the important and powerful drugs that have been introduced in recent years the dose originally recommended has been found by experience to be dangerously high, and he pleads for more care in the application of results derived from animal experiments to the calculation of doses suitable for therapeutic use. This is a very timely warning, and everyone will agree with the opinion of a scientist whom he quotes as saying, that in the case of a new drug the clinical trial, properly conducted, ought to involve a research as careful and elaborate as the preliminary laboratory demonstration of a promising activity. There are, of course, no grounds for any quarrel in the matter between workers in the laboratory and in the ward. The laboratory worker provides in the first instance certain essential information, but the necessary limitations of this information must be fully realized.

Some of the main sources of error involved in the calculation of the tolerated human dose of a drug from animal experiments are as follows. In the first place, it is well known that animals of different species but of similar weight often show a great variation in their susceptibility to certain drugs. In the second place, there is no evidence to show that the dose of a drug per kilogram of body weight that is required to produce any particular effect is, as a general rule, the same for a small animal as for a large one. Dr Martindale suggests that the dosage is more likely to vary as the body surface of the animals—that is, as the two-thirds power of the body weight—than directly as the body weight. If this be so, then the doses required to produce equal effects in an animal weighing 2 kilograms and in a man weighing 60 kilograms would not be in the ratio of 2 to 60—that is, 1 to 30—but in the ratio of $\sqrt[3]{2^3}$ to $\sqrt[3]{60^3}$ —that is, about 1 to 8. This hypothesis was put forward in 1909 by Professor B. Moore, but subsequent evidence, advanced by various writers, has been conflicting. It must, however, be admitted that the dosage is just as likely to vary with the body surface, and hence with the metabolic exchange, as it is to vary with the body weight. These considerations alone suffice to show how uncertain must be conclusions regarding human dosage derived solely from animal experiments.

Another important point is that all accurate observations on minimal lethal doses of drugs indicate that healthy animals of the same sex, and from the same stock show an extensive individual variation even in the most favourable cases, if a particular dose of a drug kills 50 per cent of animals and is tolerated by 50 per cent, then half of this dose will still kill about 1 per cent of animals. The individual variation in diseased human beings is certain to be much greater than the variation described above, and whereas the tolerated dose in animals is taken as the dose that usually produces no toxic symptoms, yet in human beings the occurrence of severe toxic symptoms even once in a thousand times is a serious matter. Probably

the chief reason why the dose of powerful new drugs is usually reduced as experience in their therapeutic effects accumulates is that the margin of safety needed to cover the extremes of individual variation in large numbers of cases is usually underestimated. It is obvious that extensive clinical experience under carefully controlled conditions is essential for the estimation of the dose of a new and powerful drug, and that tests of this nature ought always to be performed before the drug is put on the market. The point is of practical importance because it is doubtful whether this procedure is always carried out with sufficient thoroughness, and whether there is not a tendency to put new drugs on the market after inadequate clinical trials.

Dr Martindale, in conclusion, makes it plain that he has no wish to belittle the importance of animal experiments. The value of such experiments is, indeed, obvious, for these alone make the trial of new drugs possible, and few would care to undertake such a dangerous proceeding as the trial of a new chemical compound on human beings when nothing was known of its pharmacological action. The necessary limitations of the information derived from animal experiments must, however, be clearly recognized.

THE PARLIAMENTARY SESSION

THE session of 1928, which began in February, has closed with a prorogation in early August, and the Government has arranged for the next session to begin in November. This arrangement, if systematically adopted, will enable Parliament to dispose of the King's Speech and of much general business before Christmas each year, and will prevent the heaviest work of the House of Commons, both in committees and in the chamber, being crowded into the hottest weeks of summer. Next session, however, this plan will probably be modified by the taking of a general election in early summer. Though short, the session which ended last week has produced much of medical interest, most important of all, perhaps, being the disclosure that the Government's scheme for derating industrial property will be followed next winter by a bill for reforming local government. Under this bill the powers of boards of guardians and some of those now possessed by rural district councils would be transferred to county councils and to county borough councils. These latter bodies would become the chief public health authorities. In the debate on the Ministry of Pensions on the last day of the session Dr Fremantle suggested that at a later date the medical services and medical institutions of the Ministry of Pensions might also be administered by county councils and county borough councils. The local government reforms proposed by Mr Churchill will be accompanied by the introduction of block grants for health services. Mr Churchill has refused to extend to hospitals the benefits of his derating scheme. The Government has passed two Acts of special medical importance this session—the National Health Insurance Act and the Reorganization of Offices (Scotland) Act. The latter abolished the Scottish Board of Health, reorganizing Scottish health administration in a Department of Health under the immediate control of the Secretary of State, but assurances were given that the department would not become subordinate to Whitehall. Of the National Health Insurance Act the King's Speech proroguing Parliament said "A bill has been passed, based generally on the recommendations of Mr Commission on National Health Insurance, whereby the existing system will be materially simplified and improved." The Act authorizes the provision of additional benefits, but for financial reasons

the Government had to refuse the proposal of Dr Shiels that maternity benefit should include a duly qualified medical practitioner and a duly qualified midwife. Other suggested additional benefits were refused for the same reason, and the debates in committee revealed a complaint among some Labour members that too much of the funds available were spent on medical service and too little paid out in cash to insured persons. Such protests were made, for instance, when Mr Chamberlain accepted in committee an amendment adding specialist medical attendance as an additional benefit. An interesting medical debate arose in the Lords, and was re-echoed in the Commons, on the use of tetra-ethyl spirit. Regarding this the Government set up a committee, which has since issued an interim report. The most striking speech on a medical topic in the House of Lords this session was that delivered by Lord Dawson of Penn on the Dogs (Amendment) Act. Taking for his text a provision that stray dogs should not be sold for vivisection, Lord Dawson gained the approval of the House by a crushing demonstration of how antivivisectionists sinned against the light when they opposed experiments on dogs. In the House of Commons the briskest medical debate for several years arose over an Edinburgh Corporation Bill, which proposed to give powers for the compulsory treatment of venereal cases which had lapsed from attendance at corporation clinics. Despite evidence that public opinion in Edinburgh supported the bill, the House rejected it emphatically on second reading, an unusual treatment of a bill presented by a great municipality. Medical opinion in the House was divided, Dr Drummond Shiels and Dr Fremantle speaking for the bill, and Dr Graham Little and Dr Salter against it. Dr Vernon Davies has protested manfully against the narrowness with which the Admiralty judges claims that tuberculosis among bluejackets is due to naval service, but no concessions have yet resulted from his arraignment. When the Ministry of Health estimates were discussed the Minister and other speakers emphasized the value of research into rheumatic invalidity and its cause. The Ministry of Agriculture has mentioned from time to time that investigations into the causation of foot-and-mouth disease were in hand, and the prohibition of the importation of fresh meat from the Continent has been maintained. Little has been said about other branches of medical research. Small-pox statistics given by the Minister of Health from time to time have been heard complacently by the House, and the report of the Committee on Vaccination was issued too late for comment, save by Dr Fremantle on the last day of the session. No attempt was made to pass the Factories Bill, nor is it likely to be passed in the next session, though the Home Secretary has admitted that the present factory inspection staff is inadequate. Generally speaking, the session has been profitable but humdrum. It has not been marked by any attacks on the medical profession. An Act has been passed to restrict the practising of solicitors who have been struck off the rolls, but medical analogues were not drawn. Though the Dogs (Amendment) Act passed, a downright antivivisection bill to prohibit experiments on dogs failed to secure the assent of the Commons. Controversy over the medical and administrative problems of the Ministry of Pensions has practically ceased, and the affairs of that department were not discussed till the last day of the session. The Ministry of Health has not been in such smooth water, but its troubles have been lessened by the administrative ability of Mr Chamberlain and the parliamentary adroitness of Sir Kingsley Wood. The Parliamentary Medical Committee has met regularly, and has done solid work, though its members did not always speak with one voice in the House. On the whole the session has shown that the House takes a mild but friendly interest in public health questions, and that the Government is ready to allow the Ministry of Health to secure its fair share of legislation.

THE DILUTION METHOD OF SEWAGE DISPOSAL.

For many years the tendency has been, in civilized countries, to dispose of human excreta by discharge into sewers. The word "sewer" has, as a consequence, acquired in the public mind a significance which refers only to a special use of sewers. Lord Coke described a sewer as a place whence water issues—or, as is vulgarly said, "sues"—hence the word "suer" or sewer. Such were the channels regulated by the Statute of Sewers (23 Henry VIII, c. 5). The great convenience of being able to discharge filthy waste liquids into these drainage channels led in time to the construction of covered-in sewers intended wholly or mainly for the disposal of such liquids, and to the use of the special word "sewage" to denote a foul liquid, mainly of domestic origin. The great advantages, hygienic and aesthetic, to the immediate vicinity of this means of disposal cannot be overestimated. All the consequences of sewage disposal were not, however, foreseen by the pioneers of this system of sanitation, nor could they, in reason, have been, for it was only as towns grew more thickly populated and sewage systems extended that they became apparent. A foul water covered-in sewer is offensive only to the very small part of the population that is obliged to work in it, and when it is discharged into an open watercourse its effects may be confined to a very small area around the point of discharge if the volume of clean water is large relative to that of the sewage. So far as fish are concerned it is an undoubted fact that they will congregate around a small sewage outfall at a point where it discharges into a relatively large river. This may be seen at some places on the Thames. In his work on *The Principles and Practice of the Dilution Method of Sewage Disposal*¹ Professor Walter E. Adeney discusses the effects of sewage on streams. No living man, probably, is better qualified to do this—a fact which the Royal Dublin Society has recently recognized by awarding him its Boyle medal for applied science. In 1894 he began the long series of researches which are ably summarized in this book, and thereby made available for the many workers who cannot conveniently consult the *Proceedings* of the Royal Dublin Society or the voluminous reports of the last Royal Commission on Sewage Disposal. A careful quantitative study of the changes occurring in water polluted with known proportions of sewage, followed by a further study of the decomposition of definite compounds allied to those organic substances present in sewage, showed Adeney that, contrary to the views expressed by the Royal Commissioners of 1868, sewage was oxidized in water at a fairly rapid rate by the action of micro-organisms, the effects of which were not understood by the earlier workers, who had considered the problem rather too much from the point of view of pure chemistry, and had confined their attention to the end, rather than the intermediate, products of the oxidation of carbon and nitrogen. Having found that no oxidation of nitrogen occurred until great simplification of the organic matter had taken place and most of the carbon was oxidized (a result confirming the observations of the early workers on nitrification—Warington in this country, and Schloesing and Winogradsky on the Continent), Adeney turned his attention to the all-important question of the rate at which water will absorb oxygen. The speed at which any action between two or more substances will go on is clearly determined by the rate at which the supply of that body present in least amount can be replenished. Water will, at ordinary temperatures, dissolve from the air about 1/100,000 of its weight of oxygen, whilst an effluent produced by merely sedimenting sewage may take up as much as 15/100,000 of that gas.

It is clear that unless the absorption from air is very rapid oxidation in a sewage-polluted stream will go on at a very low rate. The ingenious means by which Adeney and his co-workers determined what one may believe is the limiting rate of absorption of oxygen from the air, and showed the conformity of the action with the laws of physical chemistry, is described in the book. The great value of this work is that it supplies a sufficient quantitative basis for the determination of the capacity of a stream to receive and purify, without offence, the soluble and finer suspended matters of sewage, thereby rendering the dilution method of sewage disposal no mere haphazard empirical process. This is a notable achievement, in so far as it shows to what, if any, extent more intensive and expensive methods of oxidation or other treatment need be adopted.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

Two topics of considerable interest are dealt with in the report of the National Association for the Prevention of Tuberculosis, which was presented at the annual meeting held recently in London, the first is the development of the association's educational campaign, and the second is the proposed reorganization of the Burrow Hill Colony, Frimley as a centre for the treatment and training of tuberculosis boys. The extension of propaganda work has been made possible largely by the success of the special appeal launched two years ago, and which, up to the end of June last, had brought in over £59,000. Within the past thirteen months three assistant medical commissioners have been appointed—one in July, 1927, and two early this year—to carry on educational work. Meanwhile their efforts are being concentrated on the country places, and no attempt has been made to deal with the larger towns. Some 369 meetings have been held, with an aggregate attendance of 40,000 while over 130,000 visited tuberculosis exhibitions at Shoreditch, West Ham, Whitechapel, Battersea, Ipswich, and Maidstone. Each of the three assistant medical commissioners engaged on lecture tours is accompanied by a caravan equipped with exhibits (models, photographs, and posters), literature, and a projector for lantern slides and films. One of the lecturers has been employed in Scotland, and in the course of a year has traversed the more remote parts of that country, covering the counties of Perth, Argyll, Inverness, Ross, Sutherland, and Caithness, including the Hebridean islands of Lewis, Harris, Skye, and Mull—regions in which the incidence of tuberculosis is relatively very heavy, and which are, by reason of their inaccessibility and scattered population, "backward" in matters of health. In England, during the current year, lecture tours have been carried out in the London area, Sussex, Surrey, Middlesex, Buckinghamshire, Hertfordshire, Cumberland, Westmorland, Northumberland, and the Isle of Man. The report states that the assistance given in this way by the association has been welcomed by medical men engaged in tuberculosis work throughout England and Scotland. Burrow Hill Colony, Frimley, the property of the association, was formed in 1922 to afford treatment and training for tuberculous ex-service men, many were received after the termination of the Government scheme in 1924, the main sources being the county councils of Surrey (which has filled more than half the available beds) and London. In the near future, however, Surrey patients will, it is expected, be accommodated at the new large county sanatorium at Godalming, which was opened on July 20th by the Minister of Health,² and the association has therefore been giving consideration to the future policy of the colony. Dr. F. J. H. Coult of the Ministry of Health was the author of the suggestion that the colony should be

utilized to develop a scheme for the treatment and training of tuberculous boys, a class for whom it is at present difficult to secure a suitable institution. It is regarded as undesirable that they should receive treatment with adults, and they are not eligible for children's institutions. Inquiries were made by Dr Coutts to ascertain whether, in the opinion of men engaged in the tuberculosis service, such a scheme would be helpful, and if such patients would be forthcoming in any numbers. The replies have encouraged the council to believe that the scheme would be practicable, and that the experiment should be made. Details are now being worked out in co-operation with the Ministry of Health, but it is not expected that the scheme will take effect until early next year. It is intended primarily for selected cases of pulmonary tuberculosis, but arrested glandular and other surgical cases of a suitable type may be considered as eligible. The duration of stay is not to be less than one year.

SMALL POX IN ROYAL FAMILIES

THE recent outbreak of small-pox in London gives added interest to a paper by the well known American dermatologist Dr Frank J Schamberg,¹ in which he traces the ravages of this disease among European dynasties in the seventeenth and eighteenth centuries. The House of Stuart suffered cruelly. Two of the children of Charles I died of it—the Duke of Gloucester in 1660 and, at a later period, the mother of William III of Orange. In 1677 small-pox broke out in St James's Palace, when the princess who became Queen Anne was the first to be attacked and was permanently disfigured. A newborn infant, the Duke of Cambridge, died of the disease in a few days. All readers of Macaulay's *History of England* will recall the eloquent and touching account of "the young and blooming queen," Mary, the wife of William III, who was successively regarded by the court physicians as having measles, scarlet fever, spotted fever, and erysipelas, until the correct diagnosis was made by "Radelpho, who with coarse manners and little book learning had raised himself to the first practice in London, chiefly by his rare skill in diagnostics." Two other children of James II contracted the disease—namely, James Francis Edward, known as the Chevalier de St George, who recovered, and his sister, the beautiful Princess Louisa, who died. William III only escaped because he had had a previous attack during his campaign in France, when his recovery was attributed to the method known as *per accubitus junioris*. A young and handsome page of the line of Bentinck, who volunteered to risk his life to save his master, caught the disease, and after a severe attack lived to be Prime Minister. The royal families on the Continent also suffered severely. Louis XIV lost his son the Dauphin from a violent attack at the age of 50, as well as his grandson the Duke of Burgundy. His daughter by Madame de la Vallière, Mlle de Blois, and her sister the Princess de Conti, both remarkably beautiful women, were disfigured by the disease. Louis XV, who is supposed to have had an attack of small pox in his youth—though, as Dr J D Rolleston² recently pointed out, this is more likely to have been varicella—fell a victim to confluent small-pox at the age of 64, having contracted the disease from one of the peasant girls whom he had inveigled into the *Parc-aux-Cerfs*. The death of Louis XV induced his brothers to submit to inoculation, as the royal princes in England had done some years before. Like the Stuarts, the House of Orange, and the Bonapartes, the Hapsburgs paid a heavy toll to this scourge. Joseph I of Germany, at the age of 33, fell a victim, and Joseph II, the son of Maria Theresa,

lost two wives within four years from the same cause. His second wife, Josepha of Bavaria, infected her mother in law, who for many days lay between life and death and was so terribly disfigured that her prime minister Prince Kaunitz, ordered that all mirrors should be removed from the royal apartments. It was only after her daughter Josephine and her nephew Albert of Saxony contracted the disease that she allowed van Swieten to inoculate her remaining children and grandchildren, and to introduce the practice generally into Austria. Dr Schamberg mentions many other royal personages who died of small pox, including Henry Prince of Prussia, several Austrian arch-dukes, Queen Ulrica Eleonora of Sweden, and Peter II, grandson of Peter the Great. The antivaccinationists will doubtless read with mixed feelings that since Jenner's discovery no death from small-pox, nor indeed an attack of the disease, has occurred among any of the royal families of Europe.

CONVALESCENCE

THE road to recovery is often difficult. The sick man, freed from his immediate distresses, his mind unfettered and his pains subdued, begins to be conscious of his reviving strength, and chafes at its slow return. He presents a problem which calls for both skill and tact on the part of his medical attendant. Dr John Bryant of Boston, Mass., thinks that the profession in general has shown itself apathetic towards this phase of medical practice. Little, he says, has been published on the subject, and he claims the distinction of having put together the first bound volume in any language which covers both the historical and the practical aspects of convalescence, and is exclusively concerned with the cause of better convalescent care. In this work¹ he gives an account of what has been done for the care of the convalescent in various countries, and indicates lines of development for the future. He describes in detail the convalescent institutions at Vincennes and Vesinet, which have been maintained since 1857 by the city of Paris. Not unnaturally, his interest centres on the Burke Foundation, the chief convalescent establishment in the United States, which caters for the poor of New York City. Containing over 300 beds, it has dealt with 35,000 patients since its opening in 1915. The organization of the Foundation appears to be sound and its results satisfactory. Occupational therapy takes a prominent place in its scheme of treatment. The author refers also to convalescent work in the United States Army, on which he was engaged during the war. The routine which he describes is strenuous but stimulating. In the baseball game between the "Bad Hearts" and the "Rhenmatisms," he says, the former team won after a close fight. In the army hospitals, as in the Burke Foundation, occupational therapy was found to be of great value, and many men who would otherwise have been unprovided for were enabled to leave the army well equipped for civilian life. The author devotes a useful chapter to surgical convalescence, and concludes by making an appeal to the medical profession for the better care of convalescent patients. Boston, he says, has 100 fewer convalescent beds now than it had in 1914. The solution of the problem, in the author's view, is the provision of country homes. Consisting as it does of a collection of articles published separately at different times, Dr Bryant's book is rather redundant and incohesive, but it should serve to direct attention in the United States to a field of work the importance of which is well recognized in Britain, where every important general hospital has its convalescent home.

THE REPORT OF THE COMMITTEE ON VACCINATION

WE published last week a brief note on the recently issued report of the Committee on Vaccination, appointed in February, 1926, by the Minister of Health in conjunction with the Medical Research Council. The committee consisted of Sir Humphry Rolleston (chairman), Dr I R Blaxall, Dr G F Buchan, Dr A I Cape, Dr Merivyn Gordon, Professor J C G Ledingham, and Dr J R Peard with Dr J R Hutchinson (of the Ministry of Health) as secretary. The reference to the committee was to report on (1) matters relating to the preparation, testing and standardization of vaccine lymph, (2) the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination, and (3) the methods of vaccination which are most appropriate to give protection against risk of small pox infection in epidemic and non-epidemic periods.

Preparation of Lymph

The lymph used at the present time in England and Wales for vaccination at the public expense is prepared at the Government Lymph Establishment a department of the Ministry of Health. The seed lymph used is derived from calf lymph received from Cologne in 1907. Its quality has been maintained by cutaneous passage through the rabbit, repeated transference from calf to calf having been found to lead to deterioration in the lymph and unsatisfactory vesiculation. Arm-to-arm vaccination although not expressly prohibited, can no longer be given at the public expense. Details are given of the technique of lymph production in this and other countries the methods adopted in the latter differing in minor respects only. The discovery of some method of producing lymph free from extraneous organisms would be a great step in advance, and recent investigations point to the possibility of this being ultimately attained. Thus Carr and Rivers have shown that the vaccine virus proliferates when grown *in vitro* in contact with chick embryo cells and that the potency of the virus may be greatly enhanced by this method. Again, it has been found possible to inoculate rabbits intracerebrally, and it is claimed that the product yielded (the neuro-vaccine of Levaditi) is considerable, it is said to be suitable for human vaccination and is used for that purpose in some parts of the Continent. The lymph produced by either of these processes would be entirely free from extraneous organisms.

Testing and Standardization

Regulations have recently been issued under the Therapeutic Substances Act, 1925, which governs the preparation of vaccine lymph, enjoining the employment of certain tests for purity and potency. It is directed that each batch of lymph, after mixture with glycerol or other partial disinfectant, shall be tested for the presence of living anaerobic organisms and streptococci, and if either of these is found to be present the issue of the lymph is prohibited. The question of potency has recently been under the consideration of a commission appointed by the Health Committee of the League of Nations, the reports of which were discussed at a conference held in Berlin in January, 1927. The conference accepted four tests of potency as being satisfactory—namely (1) (in test in which an opacity should be apparent in the guinea-pig's cornea seventy-two hours after scarification with a 1 in 1,000 dilution of the lymph, (2) Sobernheim's test in which a papilliform infiltration of the line of incision should appear three days after inoculation of the skin of a rabbit with a 1 in 1,000 dilution of the lymph, (3) Groth's test in which an area of infiltration and congestion should appear seventy-two hours after an intradermal injection of 0.1 ccm of lymph diluted to 1 in 1,000 into the depilated skin of the back of a rabbit, (4) Calmette-Guérin's test in which an eruption of isolated vesicles

numbering from 3 to 4 per square centimetre should appear after distributing 1 ccm of lymph, diluted in 1 in 1,000, over a prepared area of the skin of a rabbit.

Risks Resulting from Vaccination

A Royal Commission was appointed in 1889 to consider this subject and made certain recommendations, most of which were embodied in the Vaccination Act of 1898. The recommendations included the use of calf lymph, whereby an absolute security against the communication of syphilis would be afforded, the extension of the age period for vaccination to six months from the date of birth, certain technical regulations to secure cleanliness and the avoidance of sepsis and erysipelas, the use of tubes instead of dry points, and an injunction that the vaccinator should render medical attendance in cases of illness supervening if required to do so by the parent.

A comparison of the statistics prior and subsequent to the Act of 1898 shows that after the Act there was a reduction of approximately one-half in the number of deaths coded to vaccination. In the period 1886-1891, in which approximately 4,290,000 infants were vaccinated, there were 279 deaths at all ages, in 1911-1925 5,500,000 infants were vaccinated, with 128 deaths at all ages, the ratio of deaths to vaccinations in the first period (6 years) was nearly three times as large as in the second (15 years). This reduction is doubtless largely due to the recommendations of the Royal Commission towards the prevention of sepsis, but an analysis of the causes of death set out in the present report is considered by the Committee to indicate the need for further efforts in this direction. The Committee suggests that the present system of inspecting the patient on the seventh day, before the reaction has reached its maximum, should be relinquished, that the inspection should take place some time during the second week and that a second should be obligatory in the third week. It further suggests that inspection would be more satisfactory, and the means of avoiding sepsis more adequately secured, if the principle of stationary, as distinguished from the present system of domiciliary, vaccination were adopted. The outstanding differences between the two periods mentioned above are the disappearance of syphilis and the appearance of diseases of the central nervous system other than convulsions, the latter form the subject of a special investigation embodied in Part II of the report.

The Royal Commissioners stated in their final report that they had no means of ascertaining in what number of cases other diseases supervened on vaccination as a consequence of it without producing a fatal result. It appears that the only systematic attempt to ascertain and record the subsequent medical history of vaccinated persons was made by Dr Parlange Kinloch, and had reference only to the incidence of certain infectious diseases in vaccinated and unvaccinated children under 5 years of age as indicated by the admissions to the Glasgow Fever Hospital during 1910-1913. Kinloch obtained no evidence that vaccination had any prejudicial effect on a child's well-being, as judged by its response to subsequent infection. At the Committee's suggestion certain investigations have been carried out in this direction. These were made over a period of three months into the medical histories of a number of recently vaccinated children and adults and of a similar number of controls, also into the medical histories of boys vaccinated at a residential school. So far as the investigations go they do not afford any evidence that vaccine increases the liability to disease either generally or specifically. Nor does vaccine appear to aggravate a disease already established, as was shown by observations made over a period of one month into the medical histories of 206 adults vaccinated at a time when suffering from various injuries and diseases.

Central Nervous Disease following Vaccination

The suggestion that encephalitis constituted a risk of vaccination was first made by Turnbull in 1922, but it was not until 1923 that there appeared, on the death certificates of certain recently vaccinated children, terms suggesting an affection of the central nervous system other than convulsions. Subsequent inquiries led to the appointment of a committee, under the chairmanship of Sir

Frederick Andrewes, to report upon the matter. Their report, presented in May, 1925, is reproduced in full in the present report. The cases investigated by the Andrewes Committee fell into two groups: the first, consisting of 11 cases, occurring in London in the autumn of 1922, the second, consisting of 49 cases, arose in the summer of 1923, and was confined mainly to the provinces, three isolated cases, observed in London and the provinces, brought the number up to 63. That committee made extensive investigations—statistical, clinical, histological, and experimental—with a view to ascertaining whether (1) the encephalitis is due solely to the virus of vaccinia, or (2) to the action of two independent viruses fortuitously associated, or (3) to the influence of vaccination in precipitating an encephalitis in a person harbouring another virus. The main points brought out were that the number of cases of post-vaccinal encephalitis bore no direct relation to the number of persons vaccinated, on the other hand, there appeared to be an undoubted association in time between the post-vaccinal cases and the prevalence of vaccination throughout the country generally, for example, the issue of vaccine tubes in 1923 began to rise in about the middle of June, attaining its height in the last fortnight of July, and the post-vaccinal cases of encephalitis appeared in the middle of June, reaching a maximum in the first half of August. The charts also showed that the period of 1923, during which the majority of the post-vaccinal cases occurred, was immediately antecedent to a rise of poliomyelitis and polioencephalitis throughout the country. No such association in time with the prevalence of encephalitis lethargica was evidenced. With regard to clinical evidence, the incubation period was found to be relatively constant (10–12 days), in most cases the onset was rapid and the course acute, the predominant symptoms were cerebral rather than spinal, and included fever, headache, vomiting, strabismus, and varying degrees of clouding of consciousness. Where paralysis of the limbs occurred it was generally of the upper neurone. The symptoms thus indicated a diffuse inflammation of the brain, without special localization and with little evidence of involvement of the cord. The latter, it was pointed out, may have been masked by the cerebral symptoms, but should have become apparent on recovery, yet nine of the ten cases, the after-histories of which were followed up, recovered completely without the paralyses which follow ordinary poliomyelitis or the mental and other disturbances which form the common sequelae of polioencephalitis and encephalitis lethargica. Thirty-six out of 62 cases died—a fatality of 58 per cent.

The Andrewes Committee expressed the opinion that it was extremely improbable that the cases could have been due solely to the vaccine virus, but that it was conceivable that a virus such as that of poliomyelitis, which could only occasionally set up an encephalitis in a normally resistant person when unaided, might, if another virus such as that of vaccinia was present in the brain, be enabled to do so. Without expressing any confident opinion, it was along such a line that the Committee thought an explanation of post-vaccinal encephalitis might be sought. In a majority report the opinion was expressed that the evidence was not sufficient to exclude the vaccine virus as possibly the sole cause of the disease, and those responsible for the histological examination considered that poliomyelitis and encephalitis lethargica could be definitely ruled out.

The present Committee has investigated a further series of twenty-five cases, which, with one exception, conformed to the Andrewes Committee's description, it has also discussed the considerable number of recorded cases which have occurred on the Continent, and has carried out numerous experiments, the most important result of which has been the demonstration of the presence of the virus of vaccinia in the brains of certain of the fatal cases. The Rolleston Committee has discussed at length the various theories available in explanation of the occurrence of post-vaccinal encephalitis, and while it acquits the vaccine virus of being the sole cause of the disease, it is unable to exonerate vaccination from playing some part in its causation. It considers that the co-operation of vaccinia with the viruses of poliomyelitis, encephalitis, or some

unknown neurotropic virus must for the present be accepted as a working hypothesis.

The histology of the disease has been very fully worked out by Drs McIntosh, Perdrau, and Turnbull. The essential change is a perivascular and marginal demyelination in the form of a wide zone around the veins, along the ventral fissure of the cord, and beneath the pia and ependyma. The adventitial sheaths usually contain coagulated albumin, and the demyelination is accompanied by little or no adventitial infiltration. These observers would therefore refer post-vaccinal encephalitis to a definite type of encephalitis characterized by demyelination, other members of the group being certain cases of disseminated myelitis of Westphal, disseminated encephalo-myelitis of later writers, disseminated sclerosis, and encephalitis periaxialis diffusa of Schilder. Further, they consider that a condition similar to post-vaccinal encephalitis has occurred independently of recent vaccination and observed exanthemata.

Methods of Vaccination

In this country no special method of vaccination is prescribed, except that the public vaccinator must aim at producing four separate, good-sized vesicles or groups of vesicles, no less than half an inch from one another. This direction, which appears in the Vaccination Order of 1888, was based primarily on the results of a large number of observations in the last century, and the matter was further investigated by Dr A. F. Cameron and the late Dr Brownlee, in connection with the outbreaks of small-pox in London and Glasgow at the beginning of the present century. Dr Cameron's conclusions were that protection against death is directly related to the number of scars and to the area of cicatrix, and is greater when there are four divisions in a given area of cicatrix than when there are three or two, that the prognosis at any age up to 50 is more favourable with four scars than with three or two, and that protection against death afforded by primary vaccination dating mainly from infancy is not exhausted at the sixtieth year of life. These conclusions with regard to the number of scars and the cicatricial area have been corroborated by Professor M. Greenwood. With regard to the relation between the number of scars and the fatality rate, the cicatricial area remaining constant, Dr F. M. Turner has found that the correlation coefficient is low, and concludes that probably in cases with equal area of vaccination marks there is no difference in the amount of protection afforded by different numbers of scars.

Reaction of Immunity

The evidence adduced before the Royal Commission on this point was based mainly on the vaccinal condition of persons dying from small-pox. There is now another criterion available in the allergic reaction as studied by von Pirquet and employed by Leake and Thomas. The reaction of immunity was foreshadowed by Robert Cory in 1886, and the essential phenomena were known to Jenner, who, in his "Inquiry," refers to cases in which attempts to vaccinate persons already protected produced an accelerated efflorescence, which did not advance to vesiculation, but aborted. The essential point in the reaction is that the interval elapsing between inoculation and the maximum reaction in a secondary vaccination is a measure of immunity to vaccinia: the shorter the interval the greater the probable immunity. The Committee has made use of this reaction in investigating the degree of residual immunity to vaccination in persons of 18 to 21 years of age previously vaccinated in infancy. It finds that the degree of acceleration of the day of maximum reaction varies with the amount of scar area and also with the number of scars produced by infantile vaccination, further, that the effect of primary vaccination, whether in single or multiple insertion, is to accelerate the average day of maximum reaction to revaccination in men of 18 to 20 years by at least three days, as compared with primary vaccination at the same age, this period representing the average amount of immunity remaining at this age from infantile vaccination. The Committee considers that for all practical purposes the period of effective immunity may be regarded as not less than seven years.

Present State of Vaccination

From 1897 to 1925 infantile vaccination as a whole has shown a pronounced tendency to decrease, this being due to a large extent to the operation of the Vaccination Acts of 1898 and 1907, which enabled exemption to be procured on the grounds of conscientious objection. The number of revaccinations differs widely from year to year, and it is difficult to account for many of the variations. The influence of the outbreaks of small-pox in 1901-5 and in 1918 is reflected in the large number of revaccinations of persons over 1 year of age and of revaccinations at those periods. In the year 1919 a form of small-pox appeared in the provinces, invading in that year twenty-three counties characterized by a mildness so extreme as to cause many to doubt its true nature, and many cases were overlooked. As to the probable relation of the mild to the severe form of small-pox, the Committee states that it is "not in a position to determine whether or not these types constitute separate entities, or are merely variations of one disease, or if mild and severe may become transformed the one into the other. Whether or not these forms of small-pox are simple variants or are separate entities, there is universal agreement that recent successful vaccination protects against both."

The mild type of small-pox is that which has prevailed in this country for the last five years, and it has been benign with an almost negligible mortality. As a result there has arisen a marked disinclination to submit to adult vaccination. It is affirmed that vaccination is worse than the disease, that it is commonly possible to continue at work with little or no discomfort during an attack of mild small-pox, whereas abstention from work for manual workers is commonly necessary after vaccination. Certain local authorities have paid considerable sums in compensation for remuneration lost from this cause. In these circumstances, and in order to render vaccination acceptable without impairing its efficiency, the Committee recommends that an effort should be made to reduce to a minimum the amount of trauma inflicted in vaccination. It considers that it is possible to secure a 100 per cent insertion success by a technique consisting of the infliction of a single linear incision not more than one-fourth of an inch in length and confined to the epidermis, and by the simple application of lymph thereto, further, that if the smallest amount of virus sufficient to produce immunity were ascertained, it might be found possible to produce a vaccine which would cause less local and general reaction than is now met with.

FOOT-AND-MOUTH DISEASE

THE third progress report of the Foot-and-Mouth Disease Research Committee,¹ briefly noticed in our issue of August 4th (p. 218) is a bulky volume of 141 closely printed pages, relieved only by photographs of the new experimental station for work with cattle at Pirbright, and by a series of photomicrographs illustrating the histology of the foot-and-mouth lesion at various stages of its development. It opens with a most illuminating summary, compiled by the committee for the benefit of the Minister of Agriculture, of the new knowledge elicited by experts working at various centres under the direction of individual members of the committee. To the four centres where research continues as formerly—namely, the Ministry's Veterinary Laboratory at New Haw, Weybridge, the Experimental Station at Pirbright, the Lister Institute, and the Notional Institute, Hampstead—a fifth has been added at Manchester, where Professor Maitland and Dr M. Cowan Maitland, both of whom had previous experience of foot-and-mouth research at the Lister Institute, are continuing their work along certain lines on behalf of the committee.

Regret, tempered however with satisfaction, is expressed by the committee that so many members of the research staff have had to relinquish their work for the committee on their appointment to important permanent positions in the pathological world. It is pointed out that the training of competent workers takes time, and that lack of perma-

nency of these research appointments will always seriously handicap continuity of research until the scientific veterinary service of this country acquires some very considerable accession to its permanent staff of workers. Some delay has occurred in connexion with the contemplated experiments on borinos at the Experimental Station, Pirbright owing to the difficulty of securing absolutely efficient isolation of experimental units. It is hoped, however, that the new arrangements with regard to loose boxes and incinerators, the construction of which has involved much thought, will give the assurance of effective isolation, which is imperative if experimental results are to be confidently assessed.

The committee notes that many problems connected with the infectivity of cattle at various stages of the disease still await solution, but with the reconstruction of the experimental station progress in this important direction will, it is hoped, be rapid. Indispensable as the guinea-pig has proved for the elucidation of a host of fundamental questions concerning the nature and properties of the foot-and-mouth virus, it cannot, unfortunately, serve for problems of contagion in view of the inability of this experimentally infected guinea-pig to spread disease to normal contacts. Bovine experiment also must remain the final test when the value of prophylactic measures, worked out probably in the first instance on guinea-pigs, have to be assessed.

The new experimental data now available to the reader cover an extraordinarily wide range of subjects, and this hundred pages or so of small print which embody the carefully compiled protocols and research summaries by the various members of the working staff may well appeal all but the specialist in virus disease. For the others the admirable summary of the present state of knowledge compiled by the committee will afford not only ample food for reflection, but will convey the assurance that the knowledge already gained by sound, patient, and well-directed research has illuminated many dark corners, not only within the narrow bounds of foot-and-mouth research, but also within the vast sphere of virus disease in general. No student of the subject, therefore, can fail to be impressed by the mass of important data which have accumulated since the highly susceptible and inexpensive guinea-pig became available for foot-and-mouth investigation.

It is possible to sketch the new data only in the briefest form. They contain items of interest for all specialists, and there is even a sop for the therapist, who in the matter of foot-and-mouth disease rarely gets an innings. Appendix I, written by F. C. Minett, D.Sc., M.R.C.V.S., contains details of the work carried out at the Ministry's Laboratory, New Haw. These reports deal with various problems of disinfection of virus-containing materials such as filtered vesicle fluid, various substrates of wood and iron with virus dried on their surfaces, hay, hides, and manure artificially impregnated with virus, the idea being to simulate natural conditions as closely as possible. On virus contained in vesicle fluid, substances like chlorine, iodine, potassium permanganate, sodium bisulphate and certain copper salts were active in high dilution, while the phenols had only a very low potency. Alcohol, to which the virus was believed to be highly resistant, apparently owes its inactivity in great measure to the fact that the virus is protected by a film of alcohol coagulated protein, a point to which Olitsky and Boez drew attention in 1927. Why phenol is relatively so inactive is not yet explained. Formalin and mercuric chloride also possess low efficiency in these three-hour exposure tests probably owing to their slower action. In the presence of added organic matter (saliva and faeces added to small pieces of virus-containing epithelium), and with a time limit of twenty-four hours, it was found that the disinfecting value of chlorine, iodine, and potassium permanganate was reduced one-thousand times, while the concentration of phenol, cresol, and formalin required for disinfection was not appreciably different in the two series of tests. Application of these results to the disinfection of artificially contaminated hay and hides showed that spraying of model haystacks with a 1 in 1,000 solution of formalin allowed to evaporate was very effective. The result is important in view of the experimentally ascertained fact that virus allowed to dry

¹ Ministry of Agriculture and Fisheries. Third Progress Report of the Foot-and-Mouth Disease Research Committee. H.M. Stationery Office 1928. Price 5s. net.

on hair has a long life. The soaking of artificially contaminated hides with 1 per cent formalin for forty-eight hours was certainly efficient, but was prejudicial to the leather, and some other method must be sought.

In Appendix 2 the work is detailed of various members of the committee's staff at the Lister Institute—namely, Dr H B Maitland (now of Manchester), Dr T Haro (now of the Veterinary College), Mrs V M Burbury, B A, and Dr M Cowan Maitland (now of Manchester). This appendix is a very lengthy one, and contains new data under ten separate headings: (1) prophylactic vaccine prepared from the virus, (2) immunity to the disease, (3) the question of immunological types of virus which do not cross protect, (4) the duration of infectivity of guinea-pig tissues after a single intradermal inoculation, (5) the passage of virus through different animal species, (6) the treatment of foot and mouth disease in the guinea-pig with iodine, (7) data concerning survival of virus when dried on various materials, (8) the velocity of reaction of heat disinfection of virus, (9) the question of elective affinity and local immunity, and (10) the question of artificial cultivation. With so formidable an array of subjects attention can only be directed to a few of the more outstanding points.

Further work on the important question of immunization by means of formalized virus has been carried out, and it would appear that for the immunization of guinea-pigs no vaccine has proved superior to the formalized virus (contact with 0.1 per cent formalin at 26° C for forty-eight hours at pH 7.6). A single injection of this vaccine is followed by an immunity which can be recognized so soon as forty-eight hours, and it is effective up to two months. By "effective" is understood the inability of the living virus to produce secondary lesions in the body (tongue and feet) after introduction into the immunized animal by the usual intradermal route in the pad of a hind foot. Primary vesicle formation at the site of injection still takes place, and in this respect the artificially protected guinea-pig differs from the naturally recovered animal, in which neither local nor general symptoms appear in response to a fresh dose. There is a further difference in that the blood of vaccinated animals does not contain demonstrable viricidal antibodies, whereas no difficulty is encountered in demonstrating their presence in naturally recovered animals. Experiments in which large quantities of virus were given intravenously to normal, vaccinated, and naturally recovered animals, showed that in the two latter series no virus could be demonstrated in the blood after half an hour, whereas in the normal animal it could be recovered up to two or three days. It would seem, therefore, that in the case of animals vaccinated with modified virus, immunity to subsequent experimental infection is due to some profound alteration in the excitability of cell tracts (most probably of the R-E system) which are capable of responding at once to new infective antigen owing to their previous training or education by the formalized virus. The position is really on all fours with that of experimental pneumococcus or typhoid infection, and, indeed, the more these viruses are studied the more do they seem to come into line with the visible bacteria in matters of pathogenesis. The formalized virus is believed to be dead by all criteria applied, yet it may not be so. Olitsky, working with the virus of vesicular stomatitis of horses (a virus very akin to that of foot-and-mouth), has recently claimed that dermal areas into which formalized virus has been injected without apparent response can be shown by passage experiment to contain living virus. If this is so the position is not very materially altered from the practical point of view, but it would enhance the belief that only the attenuated living virus can afford solid immunity in virus disease. When Olitsky employed formalized virus that was really by all tests dead no immunity resulted.

Some highly interesting results by Dr M C Maitland deserve mention. Why is it impossible to get a lesion after injection of virus into the hairy skin of the guinea-pig? Why does virus introduced into the hairless hind pad generalize to appear again in the tongue? Is it really a question of hair? Mrs Maitland has grafted hairy skin on the hind pad: a normal response to introduced

virus occurs. She has infected a hind pad and then wrapped it up in cotton-wool. No vesicle appears. She has made infected guinea-pigs tread on wire mesh after infection and secondary vesicles have appeared on parts of the feet and toes where they do not usually do so. It would seem that pressure and the resultant irritation largely determine the propagation of virus in skin areas and not peculiarities of anatomical structure. Clinical observations in other exanthemata, such as small pox, and notably the effect of garters, will be recalled by these intriguing experiments.

Appendix 3 contains an analysis of the work carried out at the National Institute, Hampstead, by I A Galloway, B Sc, M R C V S, and S Nicolau of the Pasteur Institute, Paris. The subjects dealt with are five in number: (1) histology of the lesions in tongue of guinea-pig, rabbit, and ferret at various stages of development, (2) the distribution and localization of the virus in these animals, (3) immunity problems, (4) the influence of ultra-violet light, bile, and various aniline dyes on the virus, and (5) the effect of filtration of virus through filters of silicious earth. From their histological study of the lesion from its earliest stage in the tongue, Galloway and Nicolau conclude that the primary attack of the virus is on the epithelium. When a vesicle is about to form a few epithelial cells in the neighbourhood are found to have lost their normal shape, and to have become spherical with some accompanying degeneration of their nuclei. A few leucocytes appear to wander in even at this early stage. The degenerated epithelia and the infiltrating cells break down, and a small amount of liquid collects, which enlarges to form a vesicle. The authors observed no histological changes in the corium in the earlier stages. Inflammatory response in the corium is a later phenomenon, the authors reach the conclusion that foot-and-mouth virus possesses an essential affinity for epithelium. They have also made a further series of observations on the virus content of organs of animals at daily intervals after an intravenous dose, the animals being bled to death before examination. It was found that the blood and organs could harbour the virus on the third but not on the fourth day, whereas at a subsequent date, but not later than the eighth day, it was still recoverable from the pads and tongue. Accordingly, just as in experimental vaccinia in rabbits, although the virus is freely distributed throughout the tissues, it does not appear to be capable of active proliferation elsewhere than in skin areas. The committee points out that though some exceptional instances of long duration of infectivity are reported, the processes of natural disinfection by the physiological defences of the body lead to disappearance in a week's time of all infective virus. The fact is emphasized that where carcasses have been found to contain potentially infective virus the animals must have been killed in the early acute stage of the disease. In Germany, we are told, the carcasses of cattle killed during convalescence from foot-and-mouth disease are regarded as free from infection and distributed for human food.

There remain two important subjects to which renewed study has been given—namely, the plurality of types of foot-and-mouth virus, and the question of susceptibility of wild rodents to the disease. In previous reports attention has been drawn to the fact that two types of virus (A and O of Vallée) exist, which offer no cross protection. From cases of foot-and-mouth disease in this country the O type only has been recovered with one single exception, which proved to be A. Recently Waldmann and Trautwein of the German Commission have claimed that three distinct types occur. Samples of these three types have been compared by Mrs Burbury in cross-immunity experiment with Vallée's A and O, and it would appear that there are in truth three types, Vallée's A being identical with Waldmann's B, and Vallée's O with Waldmann's A, while Waldmann's C is a new type. There can be no question that the existence of distinct types is bound to interfere with prophylactic projects unless due regard is paid to this fact. In connexion with this question, Professor Ciucu of Bucharest working at the Lister Institute, has performed a large series of complement-fixation tests with serums of recovered or immunized guinea-pigs and an antigen prepared by a special method from the vesicles.

He has found it possible to ascertain by his method whether a given guinea-pig has been experimentally infected with foot-and-mouth disease in the past, and what particular type of virus has been used for infection. The method, it is hoped, may prove applicable to cattle. With regard to the susceptibility of wild rodents, previous reports had shown that rodents other than guinea-pigs and rabbits possess considerable natural resistance to experimental infection, and that even when inoculation led to infection they showed no capacity to spread disease to normal contacts. Further attempts to accommodate the virus to such animals by successive passage produced no evidence of raised virulence or of any increased contagiousness, so that the chances of spread of infection in nature through the medium of wild rodents appear to be very remote.

In this review attention has been drawn to only a few of the many topics which recent researches of the working staff have illuminated. The report as a whole is a most valuable document, and the new knowledge which has been gained by well-directed inquiry justifies not only the quite inconsiderable expenditure of public money voted, but a continuance of such financial support.

THE METROPOLITAN ASYLUMS BOARD

REVIEW OF THE YEAR 1927-28

EVERY year the work of that inadequately named organization, the Metropolitan Asylums Board, enlarges and becomes more various. The name which is sixty years old, merely denotes a body charged under the Metropolitan Poor Law Act to provide asylums for the sick, infirm, insane, and casual poor, but in fact a vast medical service is undertaken by the Board, through about 170 medical officers (not including specialists or consultants), with results which are of the greatest value to the whole community.

Infectious Diseases

The largest department of the Board's work is the control and treatment of infectious diseases. In the annual report just issued¹ it is stated that the number of cases of infectious disease admitted to the Board's hospitals during 1927 was 30,404—almost exactly the same figure as for 1926. There was an excessive measles prevalence last winter and the spring of the current year, but only the beginning of this is indicated in the tables, which relate solely to 1927. In a foreword to the report it is stated that London appears to experience a considerable rise in the incidence of measles every two years. The average daily number of admissions for measles to the Board's hospitals, which was 15 in November, 1927, rose to 37 in December, and remained at 45 or 50 until the end of March last. The greatest number of cases admitted on any one day was 89, on March 9th.

The following table shows the admissions for infectious diseases during 1927, for comparison we subjoin the average death rates for the two previous quinquennial periods.

	Admissions 1927	Mortality per cent	Mortality per cent	
			1917-21	1922-25
Cerebro-spinal fever	22	47.5	62.4	66.2
Diphtheria and mem- branous croup	10,320	4.03	7.8	6.3
Enteric fever	109	5.69	13.4	7.6
Measles	2,359	6.72	11.4	8.2
Scarlet fever	11,470	0.56	1.2	1.3
Whooping-cough	1,888	10.9	13.1	11.4
Puerperal fever and puer- peral pyrexia	181	12.43	—	—

An interesting table gives a record of mistaken diagnoses. In 105 cases in which the admission certificate stated diphtheria as the disease, 19 were afterwards diagnosed as measles and 86 as scarlet fever. In 139 cases in which scarlet fever was stated on the admission certificate, some

other condition, most frequently measles, was afterwards found to be the true one. On the research and pathological service side of the Board's activities it is reported that the amount of diphtheria antitoxin supplied to the Board's hospitals in the year was 270 million units. Research work is being carried out with the object of ascertaining the nature of the causal agent in measles. Another investigation is proceeding upon diphtheria carriers. Nasal douching with a mildly alkaline solution, together with vaccine therapy, has been found the best means of shortening the carrier state.

The Small-pox Outbreak

Reference is made to the outbreak of small-pox which occurred in London during the early part of the present year. Between January 17th and June 23rd 172 small-pox cases were admitted, of which, by the latter date, 101 had been discharged, 66 remained under treatment, and 3 under observation. Two of the patients died, the primary causes of death being Bright's disease and cancer respectively. The small-pox was of the mild or sub-toxic type which has been very prevalent in the provinces for nearly ten years, and which may be said to have begun soon after the conclusion of the war when international communications were resumed. Experience in London of the sub-toxic type of the disease down to the end of 1927 was favourable in comparison with the experience in the provinces. The mild form of the disease had appeared on very few occasions, considering how widespread the incidence was in the country. It is considered possible that the presence of the toxic type of the infection in London from time to time during the last eight or nine years may have assisted the work of the public health authorities by the exhibition of the possible consequences of an attack of small-pox, thereby maintaining the amenability of the people to the measure essential for the control of the disease. The 172 cases this year came from seventeen different boroughs, the greatest number from Wandsworth, where many school children were affected, from Marylebone, where all the cases came from institutions under the care of the guardians, and from Poplar.

Puerperal Fever

The Board is concentrating in two hospitals—the North-Western and South-Western—the cases of puerperal fever which it is asked to receive. To facilitate the research which is being conducted into the method of infection, arrangements have been made by the obstetric consultant, Mr. James M. Wyatt, F.R.C.S., whereby a practitioner who telephones regarding the admission of a case of puerperal fever or puerperal pyrexia to one of the Board's hospitals is asked to swab the throat of the nurse or midwife in attendance, and to forward the swab to the director of the Board's research and pathological services. Dr. Leonard Colebrook gives particulars of an investigation into cases of puerperal fever in the Board's hospitals. Some of this experimental work was embodied in the essay by Dr. Ronald Hare which secured the Katherine Bishop Harman Prize given at the recent Annual Meeting of the British Medical Association. Dr. Colebrook states that the view generally held, that haemolytic streptococci are responsible for the greater part of the serious puerperal infection, is abundantly confirmed by this investigation. A quantitative technique was employed for blood cultures, and this showed that in the most serious cases of puerperal fever the number of streptococci in the circulating blood increased in a more or less regular fashion until death. This suggests, in Dr. Colebrook's view, a fundamental difference between the pathology of puerperal fever and that of scarlet fever. In scarlet fever streptococci are rarely found in the blood, and this fact, together with the usual occurrence of a characteristic group of toxic symptoms, points to the probable operation of a specific ergo-toxin. In puerperal fever on the other hand, the frequent invasion of the blood stream by streptococci, and the absence usually of a special group of toxic symptoms, suggest that the specific ergo-toxin plays only a small part, and that proliferation of streptococci in the local lesion and the vascular system is an important and dangerous feature. Therefore the aim of treatment in puerperal fever should be primarily anti-

bacterial (that is, to kill off the streptococci in the patient's blood and tissues) rather than primarily antitoxic, as in diphtheria and scarlet fever.

Other Work of the Board

The Board has four mental hospitals, one training colony for improvable imbeciles and others, and one colony for sane epileptics. The number of patients admitted to these institutions during 1927 was 1,624, of whom 315 were received under the Lunacy Acts (more than half of these were cases of senile dementia), 81 were feeble-minded, 325 were admitted under the Mental Deficiency Acts, 285 were sane epileptics, and 618 were uncertified aged poor patients. In the institutions for pulmonary tuberculosis, 4,362 patients were admitted, 3,954 discharged, and 486 died. In comparison with previous years fewer cases are being treated, and the average duration of stay is longer, but there is no improvement in the quality of the cases coming under treatment. The view is set forth in the report that the turning point has been reached in the effort to provide sufficient residential accommodation for cases of pulmonary tuberculosis. Dr James Watt, chief medical officer of the medical tuberculosis service, declares that tuberculosis is well on its way to becoming an extinct disease in this country, but he points out the great need for protecting children from infection. He says that as it is difficult to diagnose the early stages of tuberculosis in children, the only safe course is to provide adequate treatment for every ailing child where tuberculosis is suspected, and that there is need for more co-ordinated action between the administrative authorities for education and for tuberculosis. At Queen Mary's Hospital, Carshalton, 350 additional beds are being provided for children suffering from rheumatic infections. Dr Gray Hill contributes some observations on 200 cases of rheumatism in children there. One of his points is that the special association of unhealthy tonsils with rheumatism has not been proved, he also states that rheumatic nodules are uncommon among rheumatic children of the London area, organic heart disease was present in more than half of these 200 cases.

Many other points of interest emerge from this report, as, for example, the establishment of a clinic at the North-Western Hospital for the treatment by radium of cancer of the uterus in patients received from boards of guardians. In addition to the tabulated information, a large number of contributions by members of the medical staff of the Board, dealing with specific lines of investigation, or with unusual cases, greatly enhance the value of the report.

Scotland.

Edinburgh College of Physicians Laboratory

THE annual report for 1927 of the Laboratory of the Royal College of Physicians of Edinburgh has recently been submitted by the curator, Sir Robert Philip. The report shows the large amount of work done, both in research and in reporting. Twenty-four workers were engaged in research during the year, nine were Fellows of the College, one a Member of the College, six were Fellows of the Royal College of Surgeons, and the remaining eight were granted places in the laboratory by the committee, their researches related to pathological, bacteriological, chemical, and physiological problems. The investigation into the therapeutic value of taurine in the treatment of tuberculosis, which Takekoshi believed to be considerable, has been continued, but the result of the experiments has shown that taurine, even when given in large doses, can have only a relatively slight influence. A series of experimental observations was also conducted with a view to assisting in the standardization of tuberculin. Further progress has been made in work on the mathematical theory of contagious epidemics, and the results have been published. A statistical examination of antirabic treatment in India has also been published, this work was undertaken as a study of the system of statistical representation which the League of Nations will shortly apply to the statistics of antirabic institutes throughout the world. The importance of the alkaloid harmine, to the chemistry of which much study has been devoted at

the laboratory, is the report states, increasingly recognized while work on the synthesis of benzcarbolines in general has assumed greater importance. The Chemotherapy Committee of the Medical Research Council has asked that further syntheses be carried out, samples of certain preparations have already been submitted to the committee in order that their physiological and, in particular, their antimalarial properties may be tested. Other researches, covering a wide field, have been undertaken, and a considerable amount of work has been done in the laboratory as an aid to Fellows in the prosecution of research on clinical lines by preparing sections of morbid anatomy, microphotography, etc. The amount of medical reporting work, which in the case of Fellows of the College of Physicians or the College of Surgeons is done gratuitously, has increased greatly. It appears that a very large amount of this type of work was done for Fellows on the staff of various hospitals for the benefit of their patients. The committee has therefore considered the desirability of obtaining repayment from the hospitals for work done in this way, and a tentative appeal has been sent out to the managements concerned, showing the amount of expense incurred by the laboratory in work hitherto gratuitously done for each hospital.

Evolution of Medical Practice in Scotland

THE seventieth annual meeting of the Forfarshire Medical Association was held at Arbroath on June 20th, Professor J. A. Kynoch was elected president for the session 1928-29. Dr T. F. Dewar, C.B., the retiring president, in an address entitled "Crumbs of medical biography," remarked that during the forty-two years since his graduation he had played a number of medical roles, he had been for about a decade in private practice, he had held public health appointments in counties and burghs, he had been a civil servant in an administrative department, and had also taken part in two campaigns, as a private in one and as A.D.M.S. in the other. He was therefore able to view the medical profession from many diverse angles and to appreciate the points of view of various sections of medical workers. Dr Dewar indicated the difficulties of the country practitioner, often launched upon an independent course immediately he had finished his academic training, with no intermediate period in which to acquire experience with friendly help at hand. He mentioned the methods of medical teaching in the eighties, and especially the change that had come over the teaching of public health, drains and the paraphernalia of the plumber generally had passed into the background, and the purview as applied to general illness, whether infections or not, had been largely extended. He commented on the old system whereby the doctor dispensed his own medicines, even when excellent druggists were available, and contrasted the trim work of the latter with that of tired, cold, and hungry doctors on their return from a long round. He referred to the need of more training in minor maladies and vague derangements and touched on the disappointment felt by the young practitioner on finding that he had for the most part to deal with conditions very different from those that had been described in lectures or demonstrated in the wards. Referring to the subject of the State medical service, he expressed the confident opinion that a man's diligence depended upon his character and his early training—in short, his ideals—and did not vary much whatever the mode of his remuneration.

Edinburgh Dental College

AT the recent summer meeting and prize-giving of the Edinburgh Dental Hospital and School the prizes were presented by Dr Robert A. Fleming, President of the Royal College of Physicians of Edinburgh. Addressing the students, Dr Fleming said that the dental profession held a high position at the present day compared with that of many years ago. Dentistry was closely linked with medicine and surgery in the treatment of many diseases, such as rheumatoid arthritis, dyspepsia, malnutrition, and septic poisoning. School children required much attention, and at the present day they received this to a considerable extent, but there were still very many persons in the

labouring classes who did not pay enough attention to the hygiene of the mouth, further propaganda was most necessary. The present curriculum and the pre-registration examination in particular were very stiff, but it was a noteworthy fact that the harder the curriculum was made the more it was appreciated, and the more valuable was the diploma which the curriculum brought with it. Dr. William Guy, dean of the school, mentioned that this institution like all the dental schools in these islands, and, he believed, also the medical schools, had shown a considerable falling off in the number of students entering. The reasons in his opinion were in the first place the establishment of the pre-registration examination in chemistry and physics. This operated as a deterrent because there were few schools in which these subjects were taught up to the standard which would enable a boy or girl on leaving school to pass the pre-registration examination. Parents faced with the necessity of six months or a year's delay, associated with the expense of special coaching, now inclined to place their sons or daughters into a more immediately remunerative occupation than dentistry or medicine. Another reason for the decline, he believed, was the heavy weight of taxation which now fell upon the middle class, from which most of the entrants were drawn.

Central Midwives Board for Scotland

At the examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, just concluded, 76 candidates passed out of 86 who presented themselves. Of the successful candidates 26 were trained in the Royal Maternity Hospital, Edinburgh, 24 at the Royal Maternity Hospital, Glasgow, 3 at the Maternity Hospital, Aberdeen, 3 at the Maternity Department, Royal Infirmary, Dundee, 5 at the Fife High Memorial Hospital, 1 at the Deaconess Hospital, Edinburgh, 1 at Stobhill General Hospital, 5 at Bellshill Maternity Hospital, 3 at the Western District Hospital, 1 at the Eastern District Hospital, Glasgow, 3 at the Barrow Hospital, and the remainder at various recognized institutions.

England and Wales.

Mental Disease Research in Birmingham

THE annual report of the Laboratory of the Joint Board of Research for Mental Diseases of the City and University of Birmingham contains among many items of interest a valuable account of the investigation of the bacteriological and histological condition of the post-nasal sinuses. Much time has been spent in elaborating a satisfactory technique for the collection, transmission, and culture of organisms from the post-nasal sinuses. Over 500 specimens were examined, a number of which showed pure uncontaminated cultures of important streptococci and of diphtheroids, and various organisms such as *B. proteus* and *B. pyocyaneus*. About half the number of sphenoidal sinuses examined after death showed evidence of active or previous inflammatory change. One case clearly showed the passage of organisms from the sinus membrane into bone, dura mater, and pituitary. The hypothalamic region is considered to be a likely site of bacterial and toxic invasion of the brain through the pituitary stalk, the latter structure having been shown to be invaded by organisms in one of the cases. Changes in the mucosae of the stomach were very commonly found in cases of mental disorder, and one specimen showed, by means of the special stain for Gram-negative organisms, that the whole of the mucosa was undermined with bacteria. A case of diplococcal infection of the sphenoidal sinus with associated haemorrhages in the stomach is described by the director Dr. F. A. Pickworth. In this connexion it will be recalled that an article entitled "Observations on nasal and oral focal sepsis in the etiology of gastro-intestinal and pulmonary infective diseases," by Drs. Watson-Williams and Pickworth, appeared in our issue of June 2nd (p. 931).

In the annual report of the City of Birmingham Asylums Committee Dr. T. C. Graves, chief medical officer of the City Mental Hospital, describes the steps which have been

taken to investigate the occurrence of diseased conditions of the upper air passages in patients suffering from mental disorder. These were found to be associated with all types of mental disease. In 50 per cent of the cases admitted during 1927 septic conditions were found in the upper air passages, ears, nose, and throat. In 25 per cent of the patients so admitted the conditions found were such that an investigation of the air sinuses was considered necessary, 180 patients were examined and in 151 of these there was clinical evidence of the infection of one or more sinuses. Dr. Graves remarks that in encephalitis lethargica one of the portals of entrance of the virus is considered to be the mucous membrane of the nose and throat and that the question as to the possible direct action of nose-mouth sepsis on the brain requires careful consideration. Dr. Graves discusses also the role of influenza in the production of mental disorder. He divides the cases in the causation of which influenza has played a part into two classes: the immediate class, where the mental disorder was immediately related to the influenzal attack and the delayed class, where a period of months elapsed between the occurrence of the influenzal attack and the onset of acute symptoms of mental disorder. Many of these cases required treatment of old locked-up suppuration before recovery was effected, and he regards the influenzal infection as intensifying the gradual poisoning arising from septic disease of the mouth and nose which had previously been only slowly progressive.

Growth of School Clinics in Manchester

The report for 1927 of the school medical officer, Dr. A. Brown Ritchie, to the Manchester Education Committee contains a wealth of detail illustrating the extent to which the work of his department has developed. Including re-inspections, a total of 182,802 inspections was made in the course of the year. The number of routine inspections made in the "code groups" of children was 32,503, and of this number 9,829, or 30.2 per cent, were found to require treatment, excluding cases of uncleanness and dental diseases. In his conclusion to the report Dr. Ritchie notes that the addition of new schemes of treatment and the provision of specially designed clinic buildings have made possible a great improvement in the scheme of inspection and treatment, but calls attention to the need for the further provision of special facilities—for delicate children, for crippled children, for those affected by tuberculosis, for the partially blind, and for the mentally defective. Certain extensions to existing accommodation which have already been approved will reduce these deficiencies, and it is noted that the programmes of the development undertaken by the Education Committee in other directions are heavy. Dr. Ritchie points out, however, that expenditure on exceptional children is a sound investment, producing a very high return in the form of increased physical efficiency in children who would otherwise be severely handicapped in competition with others. Perhaps the most striking feature of the report is a coloured chart illustrating the development of clinic treatment in connexion with the school medical services in Manchester. In 1915 the total number of children treated was about 2,000, in the following year the total had risen to over 5,000, and in 1917 it was not far short of 15,000. In the next two years the work doubled itself, and in 1920 the number treated was about 45,000. Since then there has been a slower but, in the main, sustained expansion and in 1927 over 63,000 children were treated at the clinics, an increase of about 5,000 on the previous year's total. Dental treatments were most numerous, accounting for about one-third of the total cases of skin diseases treated numbered approximately 11,000, defects of vision dealt with amounted to over 8,000, there were roughly 5,000 cases of eye disease, and over 4,000 cases of ear disease and defective hearing. The remainder, numbering about 13,000 were classified as "miscellaneous." It may be noted that since 1920 (after which there was a slowing down in the growth of the system) the increase in the number of children dealt with has been chiefly in the dental and "miscellaneous" group. The average number of cases of eye disease treated, for example, has been substantially lower in the second half

of this period than in the first in 1920 such cases totalled nearly 7,000, against 5,000 last year. Cases of defective vision increased slightly at the beginning of this period, but the number has been fairly constant since then, as has been the incidence of ear disease and defective hearing. The number of skin cases treated last year was less than in any previous year since 1920, last year's total was about 11,000, while the totals for 1920, 1923, and 1925 were over 14,000, and that for 1921 was over 16,000. The dental scheme as yet covers only about one sixth of the city.

Tuberculosis in Staffordshire

While the number of notified cases of tuberculosis on the registers of the medical officers of health in the area of Staffordshire, Wolverhampton, and Dudley Joint Committee for Tuberculosis at the end of 1927 was substantially the same as in the previous year, there was a slight decrease in the number of pulmonary cases, but an increase in the non-pulmonary forms of the disease. The death rate of 0.67 per 1,000 of the population from pulmonary tuberculosis was the lowest yet recorded in the area. In his annual report for last year the medical officer to the committee, Dr W. D. Carruthers, notes that of the 2,882 persons who attended for examination for the first time at the various dispensaries, more than half were sent by medical practitioners, there has been a notable increase in the number sent by health visitors, whose efforts to secure the examination of contacts have resulted in the detection of a number of cases of tuberculosis in the earliest stages. Most of the children sent for examination by school medical inspectors and found to be suffering from this disease were also in the early stages, but the report shows that adults tend to wait until the trouble has developed before seeking advice. During 1927 only 29 per cent of the pulmonary cases were in the earliest stage, and Dr Carruthers suggests that the only hope of improvement in this respect lies in the slow process of education. Of 632 pulmonary cases in all stages of the disease discharged in the course of the year, 389 had improved, 86 were quiescent, and in 157 cases there was no material improvement.

Correspondence.

THE GUILLOTINE AND ETHYL CHLORIDE

SIR,—In their article on the guillotine and ethyl chloride in your issue of July 28th (p. 149) Mr Sandiford and Dr Clayton advocate such rapid team work for tonsil removal that thirty operations can be performed in an hour. I have no means of judging the completeness of the operation. Probably the tonsils are thoroughly removed, but, in that case, such violent hurry so predisposes to haemorrhage and shock that it is nothing short of cruel to send the children out of hospital the same day. Moreover, the psychological trauma of such efficiency is terrible to imagine. Tonsil work can be leisurely, neat, shockless, and practically bloodless, so it should be, for the sake of the faith which children repose in us—I am, etc.,

July 31st

D. A. CROW, M.B., Ch.B. Ed.,
Laryngologist Royal Sussex County Hospital
Brighton.

SIR,—The well written description of Mr Sandiford's and Dr Clayton's team work in the removal of tonsils and adenoids (*British Medical Journal*, July 28th, p. 149), which varies very little from what is common in many clinics in the country, prompts me to press the merits of nitrous oxide gas anaesthesia in similar circumstances. Some years ago, after 2,000 such operations had been done with ethyl chloride in the department under Dr Ritchie Rodger's direction, a death occurred and it was decided to try gas. Since then gas has been used in some 8,000 cases with great satisfaction and no worry. The time available for the operation is rather less, but is quite adequate for an operator who is well accustomed to the work. The house-surgeons are taught the same way, it being understood that if they bungle the first tonsil they do not object to my taking the guillotine and completing the operation. Even the adult patients on the list are dealt with in the

same way if there is no history of quinsy or previous tonsillectomy, in which case dissection is resorted to almost invariably under local anaesthesia. Of course, as in the case of ethyl chloride, team work is absolutely essential—I am, etc.,

August 7th.

R. R. SIMPSON, M.B., F.R.C.S. Ed.,
Honorary Assistant Surgeon Ear Throat and
Nose Department Hull Royal Infirmary

SIR,—If it is the object of Mr Sandiford and Dr Clayton in their article on this subject to emphasize the value of team work and to extol the virtues of ethyl chloride as an anaesthetic, I agree with them. It is their method, however, that seems to me to be open to the gravest objection, and it is, in fact, no advance on the barbarous practices in vogue twenty and more years ago.

If I understand them rightly their technique, put bluntly, is this. The unfortunate child (whom we will assume is the twentieth on the list) is put in a waiting room with some thirty other victims and a nurse until he is taken to the theatre by a blood bespattered porter (for the porter has already carried nineteen struggling and bleeding children to the recovery room) and is told to lie down on the operating table. The porter holds his wrists—lightly, the authors say—while the anaesthetist, who is probably also somewhat gory, as he has held the heads of all the other victims, puts a gag in the child's mouth and telling him to breathe, claps a bag on his face. The bag is the same that has been used for all the other nineteen children. It has neither been sterilized nor emptied of the exhaled breath of the others since the day's work began.

After a brief struggle the child is ready for the "evulsion" of the tonsils and adenoids, which takes only 20 seconds, and then, struggling, bleeding, and crying (for the article says, "with a well timed anaesthetic the patient should cry, cough, or struggle on the removal of the gag") he is hurried off to the recovery room "with the buttocks tucked well up into the porter's left axilla and the head resting face downwards in the porter's right hand at a much lower level than the hips." There he regains full consciousness and what does he see? Two nurses attempting to minister to the wants of nineteen crying and vomiting children, for most children vomit some time after recovery caused by the blood swallowed.

The authors naively say, "The patient is allowed to take the position of election, some lying down, others sitting up." Who is then to dictate otherwise with a struggling child arriving every two minutes and only two nurses to look after them all? And then, after a few hours, the child is allowed to escape from this awful house of carnage and to go home and, for nights to come, to see the whole scene re-enacted in his dreams. It is no exaggeration to say that the shock to the nervous system of a young and highly strung child must do untold harm.

The system that has been in use at the Jenny Lind Hospital for Children, Norwich, for some years seems to me to avoid most of the worst points of this old and cruel technique. I submit that it is a distinct improvement on the methods employed at the Queen Mary's Hospital, Stratford, as described by Mr Sandiford and Dr Clayton, and that it is worthy of their consideration. It has the following advantages:

1. The patients from first to last never see the operating theatre nor any of those who assist in it. There is therefore no chance of them seeing blood stained hands or gowns, the sight of which must add to their anxiety and fear.
2. The longer anaesthesia obtained by the sequence of ethyl chloride and ether enables the child to be comfortably returned to bed before he regains consciousness.
3. Bleeding and consequent post anaesthetic vomiting are reduced to a minimum.
4. The use of a clean and freshly covered mask for each child is more hygienic than a rubber bag containing a mixture of ethyl chloride and another child's foetal breath.
5. Twenty cases an hour can be dealt with.

The success and smooth running of the technique depends on the anaesthetist and it is entirely due to the skill and the excellent work of Dr Branford Morgan, the honorary anaesthetist at the Jenny Lind Hospital, that it is possible to do twenty cases in an hour with comfort.

The children are marshalled in a side ward at least two hours before operation and are allowed to play and make friends with each other. Half an hour before operation they are undressed and lobed in warm flannel gowns kept for the purpose. They are given liq atropin sulph. mii by the mouth, which avoids the frightening ordeal of a hypodermic needle prick, and seems to act as well. They are then all taken to a room as far as possible removed from the operating theatre, where there will be little chance of them hearing what is going on, and are left in charge of a nurse.

The work then begins. Adjoining the operating theatre but separated from it by a tightly fitting door, and entered by a second door is an anaesthetic room, in which all anaesthetics are administered.

The anaesthetic used is ethyl chloride followed by open ether given on an ordinary mask covered with several layers of gauze. As each child is brought in by a nurse—who remains with him until he is fully anaesthetized—he is put on a trolley and induction is commenced. To make it more pleasant the ethyl chloride used contains a small percentage of eau-de-Cologne. Struggling is the exception. When the child is fully anaesthetized the nurse and anaesthetist take the trolley into the operating theatre and lift the child on to the table which has been already prepared and has a sandbag so placed that it lies beneath the patient's shoulders. This is most important for reasons that will presently be seen. The average time taken to secure complete relaxation is 80 to 120 seconds.

The anaesthetist then stops the administration by removing the mask, and, opening the gag that is already in the child's mouth returns with the nurse to the anaesthetic room leaving the child's head to be held by the theatre sister, and the responsibility for an adequate entry to the surgeon. It will be noted that by this means neither the anaesthetist nor the nurse assists at the operation, and so cannot become blood bespattered.

The tonsils and adenoids are then removed much as described by Mr. Sundford, except that, instead of being evulsed, they are separated from their capsule by a combined movement of the index finger of the free hand and the blade of the guillotine. The method is difficult to describe but easy to carry out. The essence of the manoeuvre is a scissor action, the finger sweeps downwards and the guillotine, by an extension of the wrist, upwards. Shock and haemorrhage are thereby greatly reduced. After the removal of the first tonsil a sterile swab is inserted between the pillars of the fauces, and left there until the second tonsil has been dealt with. The child is then quickly turned on his side, the swab taken out, and the adenoids dealt with while the head is kept in a dependent position over a basin of cold water. The insertion of the swab together with the presence of the sandbag under the shoulders, effectually prevents all blood entering either the gullet or trachea. Post-operative vomiting is therefore rare.

After the bleeding has been arrested by sponging the patient's face with cold water, the gag is loosened by the sister but not removed. Two nurses lift him on to a trolley with the gag still in his mouth and wheel him to the ward where he is received by a sister and put into a warm bed, in which he is pleased to find himself when he regains consciousness some minutes later. The staff of the ward varies with the number of cases dealt with but usually it is a sister and two nurses to every twelve patients.

The moment the adenoids are removed the surgeon starts washing up for the next case. As soon as the patient leaves the table the theatre sister takes the dirty Mackintoshes and used instruments to the sink, and leaves them there to be cleaned and sterilized by one of the theatre nurses on her return from the ward. She then washes her hands, and puts a fresh basin containing the sterile instruments in a stand at the head of the table. By this time the next patient is ready, and all in the theatre are in readiness to receive him. The second theatre nurse, on her return from the ward with the trolley, recovers the anaesthetic mask with sterile gauze and hands it to the anaesthetist as he leaves the theatre to start the next case. The staff required is a theatre sister and two theatre nurses, a ward sister and a variable number of nurses—not less than two for a dozen children, a nurse to be with the waiting children, and a nurse to assist the anaesthetist.

There are two other statements about which I am in variance with the authors. They say that the area of relative baldness frequently seen on the back of the head of a child of 6 months is a sign of adenoids, and is the result of the anaemia produced causing restlessness during sleep. This is an assumption not borne out by fact. I think most ward sisters and others used to babies will agree with me that it is the healthy and contented babe who lying on his back most of the day looking to the right or left at all that goes on around him, wears his hair off, and not the adenoid child.

Again, they dogmatically state that curache occurring after a lapse of twenty-four hours is due to infection. Curache a week or ten days after operation is a common complaint. It is only noticed immediately after eating; it affects both ears, and a careful examination fails to reveal either injected drums or impairment of hearing. Spraying the site of operation with hydrogen peroxide gives immediate relief. Undoubtedly it is a referred pain, and not inflammation.—I am, etc.,

Norwich July 31st.

N. STUART CARRUTHERS

USIS OF SUBCUTANEOUS INJECTIONS OF OXYGEN

SIR,—In your issue of August 4th (p. 195) Dr. T. S. Kirk states that if oxygen—say about 150 c.c.—is injected subcutaneously into a rabbit, it is rapidly absorbed. I have performed very many injections of different gases into various animals, chiefly rabbits, to endeavour to study tissue oxygen tensions, and my results have been published in numerous papers, mostly in recent numbers of the *Journal of Physiology*. I found that after injection of 1,000 c.c. of oxygen under the skin of a rabbit some gas is still present seven days after the injection. The processes following the injection are not simply concerned with the absorption of oxygen, the most rapid change is the passage of carbon dioxide from the tissues into the injected gas until the pressure of carbon dioxide is about 6 per cent of an atmosphere. Also, nitrogen diffuses out slowly from the tissues until eventually it forms about 88 per cent of the gas present. Oxygen is being absorbed, but somewhat slowly, and I am certain that some of the original oxygen will be present in the tissues several days after the injection of 1,000 c.c.

I have also injected 200 c.c. of oxygen under the skin of the back of my own forearm, and also of that of another subject, and some of the gas was still present two days after the injection. The gas spreads out readily under the skin if the limb is moved much, and then the gas is not easily detected. I very much doubt Dr. Kirk's suggestion that the improvement in cases of pneumonia, etc., following the injection of a few hundred cubic centimetres of oxygen under the skin is due to the relief of anoxaemia. An adult man uses 250 c.c. of oxygen a minute, and it seems impossible that a few hundred cubic centimetres injected under the skin would be sufficient to relieve an anoxaemia lasting over twenty-four hours—quite apart from the fact that the oxygen is so slowly absorbed when thus injected. Some other reason for the improvement in his patient's condition must be given.

There is a great deal of research and literature on this question of relief of anoxaemia, and Dr. Kirk has made no reference to it. Recently Dr. Whitridge Davies proved that subcutaneous injection of oxygen into animals does not relieve experimental anoxaemia.—I am, etc.,

Hampstead N.W.3 Aug. 4th.

J. ARGYLL CAMPBELL

SIR,—I note with great interest that Dr. Kirk finds that the incidence of post-operative vomiting and chest complication has diminished since oxygen has been given to his cases as a routine ending in anaesthesia.

When house-surgeon I noticed that the patients to whom I gave oxygen with their ether had a much smoother time both during operation and after leaving the table. So I then made it a custom to "flush them out" further with oxygen at the end of each anaesthetic, and after that never had any difficulty with them between their leaving the table and reaching the ward. Giving it during anaesthesia was a great help, particularly with soldiers.

I continued this on becoming obstetric officer, feeling that it made for smooth sailing and minimized chest trouble after, but did not appreciate the diminution in vomiting until my ward sister asked, "How is it that your cases hardly ever vomit—what do you use?" I assumed then that some of the credit must be due to the oxygen and the rest to the routine pre- and post-operative rectal glucose feeding given.—I am, etc.,

Harrogate Aug. 4th.

MURIEL KIPPES

DIAGNOSTIC METHODS IN RELATION TO
CANCER

SIR,—I see it stated in the *British Medical Journal* for July 28th (p 170), in the sectional proceedings of the International Conference on Cancer, that, according to Professor I C Dodds, in conjunction with Dr W Lawson, on methods for the diagnosis of cancer by a study of the blood, "the Shaw-Mackenzie reaction, as well as the Ringold method, had been investigated, and proved to be non specific." So far as I am concerned, this is only a repetition of statements put forward by others in various quarters last year, to which I replied.

As I have pointed out on various occasions in the *British Medical Journal* and elsewhere the power of the serum to increase fat-splitting when added to pancreatic extracts and to pancreatic juice itself is decreased in cancer compared with the action of normal serum. This I described in 1913 at the International Congress of Medicine in London, and detailed further in the *Journal of Physiology* in 1915. This reaction, as subsequently employed, frequently enabled a positive diagnosis of cancer to be made in obscure cases or the presence of cancer to be excluded. It formed the basis, further, of the turbidity blood tests which I have described also. In neither case have I claimed that the reaction or test is specific. I have repeatedly stated that they are not but of practical utility as an aid in diagnosis, as in the non specific Wassermann test.

In this connexion it seems only right that I should mention that in February, 1927, Professor Dodds, on his own initiative, sent to me at the Ross Institute and Hospital a series of bloods, labelled 1, 2, 3, 4, 5, 6 "some of them said to be from cases of malignant disease, whilst others were from non malignant cases," on which specimens he requested my diagnosis, stating that "the actual key to the results is being held by a third party." I was not at the institute that day and being much occupied otherwise I was compelled to write that I could not undertake the several blood examinations, moreover, that the blood differentiation in labelled specimens from various sources without knowing the nature of the case had already been done in numerous tests of blood specimens from hospital cases and my results published. My laboratory assistant, Mr Press however, proceeded to examine the specimens on his own account, and, as ascertained later, the results proved correct in five out of the six serums—namely, four malignant and one non-malignant. The single error occurred in a non malignant case (hydrocele), which gave a "positive" reaction.

The serum in this case was noted to be initially cloudy, which, as I have pointed out, leads to error in the turbidity test. Had the precautions been adopted which I have detailed in my papers I doubt if the error in this case would have occurred. As to whether similar precautions were pursued in the cases investigated by Professor Dodds I do not know. This factor of error gave me great trouble in the first instance, and though I know it can be eliminated in certain cases, it cannot be eliminated in all cases of non-malignant bloods. It is this which has appeared to me to bring cancer into the group of diseases or conditions associated similarly with defective fat-metabolism.

The importance of a "positive" reaction when present in post-operative cases, which I have particularly noted in breast cases in patients apparently in good health without outward manifestation, is the real concern. It is here not merely a question of diagnosis, and the question of specificity in such cases can hardly count.

The obvious indication is treatment to increase the lipolytic power of the serum or to remove inhibiting factors, and in this direction the employment, for example, of sodium oleate and other activators of lipase with their known effect of increasing the circulating lipase, in the hope of reducing or preventing recurrence. The decreased action of the serum on lipase in cancerous subjects compared with the action of normal serum is no longer in abeyance or doubt. The conclusions I came to originally have been confirmed recently in independent investigation by Professor W C M Lewis and R F Corran (Liver-

pool), for which I am extremely grateful. Though not necessarily diagnostic, this change in the blood from normal in cancerous subjects is thus a fact, and its significance and bearing on treatment independently shown further by them, in similar action by other therapeutic means—I am, etc.,

J A SHAW-MACKENZIE, M.D. (Lond)

London S.W. 15 Aug 1st

GASTRIC SECRETION OF NEUTRAL CHLORIDE

SIR—We are growing rather tired of the various claims with regard to duodenal regurgitation and the gastric secretion of neutral chloride. In the latest communication on this subject in your issue of July 28th (p 177) Dr Hansman appears to be labouring under the false impression that he and his co-workers were the first to state that secretion of neutral chloride by the gastric glands may play a part in gastric secretory activity. This conception, like many others, is an old one.

With regard to Dr Hansman's denial of any knowledge of our work until its publication, we can only say that a full report of our findings was delivered to the Biochemical Society in November 1926, many months before Dr Hansman's paper appeared, and that we have definite proof that he is aware of this. Since that time the subject has been discussed throughout a wide circle in London and elsewhere.

The paper in question is only one of several papers published recently on the subject of duodenal regurgitation, it was not referred to in our publications in the *Journal of Physiology* for the reason that our papers were completed before Dr Hansman's publication appeared. Further, we are not satisfied that Dr Hansman's arguments are quite sound, in our opinion they are open to criticism. It is our intention to discuss, at a later date, Dr Hansman's work along with that of other authors in a more complete review of the subject this will appear towards the end of this year.—We are, etc.

H MACLEAN,
W J GRIFFITHS

St Thomas's Hospital S.E.1 July 31st.

SKIN AND SUN

SIR—There is one organ of the body occupying two to three thousand square inches of space and weighing several pounds that is directly and intimately associated with practically all the great systems such as the circulatory and excretory and that has more functions than most of the other organs put together. It has, however, been neglected for centuries, except by the manicurist, the chiropodist and the dermatologist. However, in these days of actinotherapy this delicate and influential organ is slowly coming into its rightful place. The clinician is awaking to its value in diagnosis and its importance as a medium of treatment but it is the helio-therapist who is realizing, as never before, the surprising direct and indirect effects which the proper contact of sun and air with the whole skin can produce in the body generally.

I have had experience for three years in giving (real) sunlight treatment and taking sun baths under what, I admit are ideal conditions so far as altitude, sunshine, hours and climate generally are concerned. This experience, and my reading on the subject, convince me that we are on the verge of great discoveries in this particular. I have seen and personally experienced some of these effects, such as the increase in basal metabolism, improvement in weight, rise in blood pressure and temperature, change in appearance and texture of the skin itself, toning up of muscles, as well as the actual cure of disease.

I am not a crank or a faddist and am well aware of the danger of overstressing the value of any new method, I am also fully alive to the practical difficulties surrounding the matter especially in England, but I ask the following questions in the hope that they will receive full consideration and due support.

1. Have we not by our towns, smoke, clothes, houses, windows, climate, and civilized conventions starved our skins of sunlight shut them off from healthy contact with moving air, and by

systematic neglect and bad treatment hindered them from playing their important part in the maintenance of normal health?

2 May it not be that this condition of things is directly responsible for many of the diseases from which civilized people suffer?

3 Is it not possible that here lies the way of escape from the ravages of tuberculosis, cancer, and other diseases?

4 Should not the following axiom of Leonard Hill apply to disease of many kinds? 'The properly fed and well sunlit person need never fear the cold' (substitute 'disease').

5 Knowing as we do the great increase brought about in the resisting powers of the tissue by the graduated action of sun and air on the skin does not this open a wide field for active preventive medicine?

If these questions do not provoke both criticism and approval I shall be disappointed—I am, etc.,

LEWIS E. HERTSLET, M.R.C.S.

Florida, Transvaal June 26th.

THE CURSE OF NOISE

SIR,—Many members will rejoice to observe that at the meeting of the British Medical Association at Cardiff the Association has, at long last, taken up the question of unnecessary noise. Some noises are, however, enforced by law, for instance, a man may not beg quietly, he must make a noise on some "musical" instrument, or must "sing" if he is to be permitted by the police to ask largess of His Majesty's lieges. Further, I am told by clergy that the law insists upon the ringing of a bell before service, and this is taken as an excuse for the intolerable nuisance created by the indiscriminate ringing of church bells. Again, the law demands that motor cars "must give audible warning" of their approach, although it is agreed by the vast majority of experienced and skilled drivers that about 99.9 per cent of the present horn blowing is unnecessary. An Act of Parliament therefore appears to be necessary before anything can be done to stop unnecessary noise, which the Association has pointed out is most prejudicial to health, to well-being, and to the proper functioning of the brain. I therefore venture to suggest that the Council of the Association promote a bill in Parliament with the help of the medical members of Parliament, not only to repeal past enactments which permit or enforce noise, but also to make unnecessary noise of all kinds punishable by law. If the Association succeeded in this public work it would enhance its own prestige and its influence with the public, would set a good example to the world, and would win the acclamation of city-dwelling mankind—I am, etc.

London SW1 Aug 2nd.

HARVEY HILLIARD

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

On August 3rd Parliament was prorogued till November 6th, when a new session will begin. Before prorogation the Royal Assent was given to the Finance Act, Dogs (Amendment) Act, Petroleum (Amendment) Act, University of Reading Act, Slaughter of Animals (Scotland) Act, Shops (Hours of Closing) Act, Rag Flock Act Amendment Act, Merchant Shipping (Lane Throwing Appliances) Act, and many other statutes. In the King's Speech proroguing Parliament, which was read by the Lord Chancellor, reference was made to the passage of the National Health Insurance Act, to the steady progress in housing, and to the stabilization of pensions.

Appropriation Bill

Ministry of Pensions Administration

During the third reading of the Appropriation Bill on August 3rd the House of Commons discussed Ministry of Pensions administration. Mr F. O. ROBERTS gave details of cases which he argued should have been accepted by the Ministry as due to war service.

Dr FREMANTLE remarked that the Ministry of Pensions was an influence on the health of the nation but was divorced from the general health services of the nation. The Ministry must some day come to an end as a separate entity. The House should consider to what extent the Ministry should be changed. After most pensions had been stabilized this largely became a medical question. Sooner or later the responsibility for institutions and for personnel would be transferred. The natural body to complete and wind up the service would be the Ministry of Health but there had been a reluctance to imagine the fusing of the pensions service with the service of the Poor Law guardians. The Government however proposed next session to transfer the whole Poor Law system to larger authorities and that would give a new

envisagement of institutional treatment and of the public health. There was a *prima facie* case for halving these large authorities would be the bodies fitted to take over or to operate the services of the Ministry of Pensions. The Minister of Pensions would have to consider the future of his gradually diminishing personnel. Eminent medical men had given themselves up to the pensions service, and it would be difficult to turn them out and give them no future at all. Similarly, it would be bad to see Ministry of Pensions institutions contracting and becoming less efficient and for the Minister to have to prepare big schemes for their fusion. Therefore the Ministry of Pensions should envisage the possibility of gradually co-operating with the Ministry of Health and with the counties and county borough councils for a gradual fusion of the two services. In so far as pensions were concerned the Ministry of Pensions would naturally retain its liability. The Minister of Pensions should consider how he could co-operate with the Minister of Health and the civil authorities by taking analogous cases from the civil population into his institutions.

Dr DAVIDSON SMITH said the Minister of Pensions had that week announced a decision to stabilize pensions but in any event pensions could not have been reduced till 1931, probably not until 1932. Ever since 1920 reinterpretations of the original warrants and new regulations had diminished the privileges of ex-service men and had excluded many who were obviously entitled to compensation. Any number of cases had gone through his hands where men who had undoubtedly suffered seriously in health because of the war received no pension, or a miserable pension. The pensioner was left to fight for his rights. The Ministry of Pensions turned down not only the opinions of panel doctors, many of whom were extremely indignant but also the opinions of well-known specialists. He was not sure this was done by the medical men at the Ministry of Pensions, medical men were not supreme there. The Ministry should give more heed to the opinions of conscientious medical men who knew the patients and, in many cases, knew them before the war.

Mr MONTAGUE said Dr Fremantle's suggestion of the use of the Ministry of Pensions to provide an efficient medical service for the civil population was a big advance towards the Labour party's view in regard to medicine and the nation.

Major TAYLOR said the stabilizing of the disability pension was the most vexing problem with which the medical profession had to deal. It was almost impossible even for the most expert medical man to determine in many instances whether the disability was due to the war or not. Disabilities if there were a doubt should be attributed to war service.

Major TRYON said the Ministry had now given final awards to over 300,000 men, but in certain cases of disablement final awards were not given in the interests of the men. The problem of artificial limbs for ex-service men had been satisfactorily settled. The State was expending £3,000,000 a year on ex-service mental cases. He agreed with Dr Fremantle's praise of the staff of the Ministry. The country did not realize the wonderful work done for the sick and disabled by the medical staff of the Ministry. Medical science had been advanced by them. Major Tryon was glad to say that in a hospital which had hitherto done much work for ex-service men the great experience gained about the loss of limbs had been used to help railwaymen who in civil life lost their limbs. In that way the Ministry hoped to carry on the medical experience gained so that it might be of assistance in civil life to other sufferers. The proposal to throw on the Ministry the onus of proof that disability was not due to the war was a dangerous proposal from the point of view of the ex-service men and would provoke a reaction against the present rates of pension.

Mr BROAD said that where a panel doctor had been given charge of a man for his war disability he should have as much respect and recognition from the Ministry as its own doctors had. It was an insult to the panel doctors that their word was not taken when the responsibility was thrown on them.

The Appropriation Bill was read a third time and the prorogation of Parliament followed.

Ministry of Health Vote.

In the House of Commons, on August 1st, debate arose on the Estimates for the Ministry of Health. Mr LAWSON protested that the Minister of Health had reduced the grants for milk to nursing mothers. In Poplar this grant had been cut down from £6,033 to £3,233. These grants had halved the death rate among babies in that district and had considerably reduced the deaths among mothers. Discussion followed on the treatment of casuals.

Dr FREMANTLE said there was a general support of the Ministry of Health and cordial approval of its record. The report from the Departmental Committee on Vaccination had been presented and it would be wrong to let the session close without emphasizing the importance of that report. That Committee had been appointed because a state of affairs was coming about which the medical profession pointed out as a great danger. The number of unvaccinated people was large and was increasing each year in proportion to the population. Among the school population less than half were now vaccinated and the number who sought vaccination and were therefore protected in later years was still smaller. Vaccination was a small price to pay for protection from an alarming disease which might be a scourge to this country as it had been in the past. Other countries were infinitely keener in seeing that no contamination from small pox reached their shores and the fact that there was small pox in this country was a constant menace to our relations with other countries. The report raised the problem of the occurrence in the period after vaccination of certain unfortunate cases of nervous disorder which some had stated to be possibly due to the operation of vaccination.

The report dealt thoroughly with these cases and showed they were a small number compared with the total number of vaccinations. The number of cases investigated by the Committee was 62, of which a considerable number were fatal. Among 314,000 primary vaccinations in one year 62 was a small number. The deaths from vaccinia over a period of fifteen years had only been 0.001 per 100 vaccinations. The Committee could trace no cases of this kind in the year 1924 though the records of the results of vaccination were complete. The Committee found some of these cases in 1922 and 1923 and it found a close association between these cases and the epidemics of encephalitis lethargica and poliomyelitis. The Committee came to the conclusion that just as children suffering from scarlet fever measles and other ordinary complaints were more susceptible to poliomyelitis, so those who had been vaccinated were more liable to be attacked by these two diseases in a time of epidemic. The Committee hoped that further research would find out exactly what caused this complication and the House might hope that the country would not see again symptoms which were accidental both geographically and in years. The Committee further suggested that vaccination should be by a puncture instead of by scarifying, that one puncture might suffice, and that a milder vaccine might be used. When the House discussed the future of vaccination it must recognize that smallpox was considered apart from other diseases and apart from the rest of public health. Why should the measures dealing with smallpox be in the hands of the guardians while all other public health measures were in the hands of the public health authorities? Medical officers of health had often suggested that the administration should be transferred to the sanitary authority or to the county councils. In the proposed reorganization of local government next session and the abolition of the guardians these powers of vaccination and the responsibility for vaccination would go to the authorities of the counties and of the county boroughs. They looked forward hopefully to seeing the protection of the community from smallpox by a larger authority with officers of a wider experience to administer the law. Turning to the Ministry of Health Estimates as a whole Dr. Fremantle said they amounted to £20,000,000 of which over half was due for housing. Less than £10,000,000 was provided for the treatment or prevention of disease though the prevention of disease had resulted in an enormous improvement in the health and efficiency of the people. When a clear case was made out for extra expenditure by the Ministry of Health the money should be granted. In reference to Mr. Lansbury's complaint about the reduction in the grants for milk Dr. Fremantle said that in certain definite areas the milk had come to be taken by ordinary healthy people to relieve them of an item in their domestic budget. They must focus attention on the provision of houses for the very poor and on the clearing of slums.

Mr. HARRIS said the money spent on health insurance had resulted in wonderful improvement in the health of the country. The work on maternity and child welfare was not less important. In Bethnal Green, the poorest and most overcrowded borough in London the infantile mortality had been reduced to 57.7 per 1,000 from 129 per 1,000 in 1918. That reflected great credit on the medical officer and his loyal servants. The expenditure on milk had been well justified in Bethnal Green and was not on an extravagant scale. He regretted that Mr. Chamberlain now said that milk should not be given to mothers who were in receipt of Poor Law relief. The declining infantile mortality in Bethnal Green was largely due to the free distribution of milk.

Captain BOURNE said the total cost of sanatorium treatment for tuberculosis in this country was between £4,000,000 and £5,000,000 per annum yet the Minister of Health had admitted that his department had no statistics showing how many people who passed through sanatorium treatment were cured. In Oxford recently an effort had been made to deal with some tuberculous cases by tuberculin treatment. The Ministry should see whether it could be combined with other treatments to help the 300,000 people who were suffering from tuberculosis yet could not obtain sanatorium treatment.

Mr. BRIANT condemned the housing and sanitary conditions provided for pickers in the hop fields. The regulation for the separation of the sexes by screening was almost invariably neglected, and the absence of proper latrine accommodation was described as discreditable. So long as this matter was placed entirely within the power of the local authorities nothing would be done, however strong the medical officers might be.

Mr. SHEPHERD speaking on the treatment of casuals said half the men on the road were suffering from disease caused by undernourishment. Men detained in casual wards should get the same meals as ordinary inmates of the workhouses.

Mr. JOHN said the action of the Minister of Health in reorganizing the Welsh Board of Health had given the impression in Wales that the Board had been deprived of its former status. Instead of the Board three officers in Cardiff were carrying out the work as civil servants under the direct control of Whitehall with no provision for a duly appointed chairman. Mr. LEON CROSSER supported the protest.

Replying to the debate Mr. CHAMBERLAIN said the Welsh Board of Health had never been an executive body. On the average it had only met three times a year during the last nine years. He regretted that it was necessary to reduce the grant for milk. In some areas the expenditure on it had been £20 per 1,000 of the population. Other authorities gave none at all. The Ministry had not forbidden any local authority to give as much milk as it chose. It had to limit the amount of the Exchequer grant but he did not admit this economy would undo what had been done for the preservation of infant life. The Ministry of Health had little power with regard to hop-picking. What was needed was the education of public opinion. He had done what he could to induce local authorities to adopt model by-laws. In answer to

Captain BOURNE, Mr. Chamberlain said the Ministry had not figures from sanatoriums all over the country to show what happened in people after they were discharged but the Brompton Hospital Sanatorium had supplied particulars of between 3,000 and 4,000 patients who had been discharged. These showed that, of the moderately advanced cases, after five years 67 per cent of the males and 67 per cent of the females were alive and apparently in good health. After ten years 38 per cent of the males and nearly 50 per cent of the females were alive and in good health. This indicated that money spent on sanatoriums was well spent. It prolonged the lives of many people saved those of many others, and diminished the infection among the healthy.

The House then carried the vote for the Ministry of Health by 255 to 132.

Scottish Board of Health

On July 31st the House of Commons considered in Committee of Supply a vote for the salaries and expenses of the Scottish Board of Health. Mr. W. ADAMSON said that he wished to discuss the critical condition and physical deterioration of the people in certain areas of Scotland, due to the inadequate provision made for them by the Scottish Board of Health. The main cause of this distress was unemployment which was even worse in Scotland than in England. Dr. DRUMMOND SMITH wished to know what was the position with regard to the vacancy in the medical membership of the Board. It had been known for a long while in advance that Sir Leslie Mackenzie was going to resign. Could the Secretary for Health intimate when his successor would be? He sincerely hoped that when the appointment was made it would be found that a member of the present staff had been promoted to the position. The questions of milk supply and tuberculosis were dealt with in the report. Undoubtedly a very great improvement had taken place in the quantity of licensed graded milk, but it still amounted to little more than 1 per cent of the whole milk supply in Scotland. The nomenclature of the grades was very misleading. There was no doubt that Grade A, which was only the third of the qualities was considered by many people to be the first quality while the tuberculin tested milk had not got the position in the public mind which it ought to have because of the confusion of Grade A milk with that of the highest quality. Was the position satisfactory with regard to pasteurized milk? If pasteurization was carried out effectively this milk was safe, but there was a great liability for pasteurization to be done ineffectively and so to become a danger rather than a help by misleading people as to its goodness. The report did not deal with that point. The report stated that last year 2,240 animals mostly cows were condemned as tuberculous compared with 1,852 in 1926. The Board of Health considered that the increased number was a sign of increased efficiency in the inspectorate, and if that was so he was glad. It also showed that there was still a substantial amount of tuberculosis among the cattle of Scotland and in view of the danger to young children it was well that effective steps were being taken to deal with the matter. The Empire Marketing Board was now publishing placards inviting people to use more milk but he would hesitate to recommend anyone with young children to use ordinary milk unless he was satisfied that that percentage had been reduced almost to vanishing point.

The report contained a chapter on venereal disease. It was very cautiously written but it showed that the technical heads of the department were not at all satisfied with the position. Some £60,000 or £70,000 was being spent in Scotland alone on this matter and something like £600,000 throughout the kingdom. Yet in Scotland the proportion of defaulters was 51 per cent. That showed an appalling waste of public money. The local authorities in Scotland were of opinion that the present arrangements were not satisfactory or efficient. The question of the co-operation between hospitals was being very carefully considered by many bodies in England and Scotland. The old voluntary hospital managers were very much concerned with the present position and the question of co-operation between the voluntary and municipal hospitals was bound to arise in connexion with the various Government schemes. In Aberdeen there was an arrangement that seemed to be very desirable. The parish councils there had handed the hospitals over to the public health committee of the town council and the whole of the public health accommodation there was being administered by one authority. In Glasgow also there was a similar working arrangement. Many of the Poor Law hospitals in Scotland were not well equipped or adequately staffed and the association with the municipal departments and with the staffs of the various voluntary hospitals was bound to increase their efficiency. The report of the Mackenzie Committee stated that there was a shortage of 3,600 beds in Scotland two years ago and the position was not any better to-day. Did the Minister consider that final arrangements had now been made, or were likely to be made to provide a proper number of beds? The Scottish Committee of the British Hospitals Association had set up five local committees for co-ordinating the various hospital activities and there was also a liaison committee between that body and the department. There was a danger of magnifying to a great extent the voluntary principle and of saying that it must be preserved at all costs. The first consideration must be the efficiency of the hospital services and the supply of an adequate number of beds. While they acknowledged the good work which the voluntary hospitals had done they regarded the voluntary agent as being the pioneer. When the necessity for the work was evident it should be done by the public authority so that the necessary medical attention was given to all classes of the community.

What had happened to the report of the Departmental Committee on Maternal Mortality and how many of its recommendations had been put into operation? There was no doubt

that this subject must ultimately be dealt with by municipal maternity services, and by ensuring co-operation between doctors and midwives, and between the ante-natal services and the other public health services. Was the Board of Health urging local authorities to put into operation the whole of their powers for feeding necessitous school children? With all the poverty and misfortune in Scotland there was money enough to feed the children. The same considerations applied to the questions of the dental treatment of school children, of treatment for adenoids, tonsils, and so on.

Dr. ELLIOT replying to the debate said that the Scottish Board of Health was not flinching from drastic legislative action to make sure that the milk supplies were as pure as could reasonably be managed. In reply to Dr. Shiels a question as to the medical member of the Board of Health he said that everyone knew that Sir Leslie Mackenzie had now retired. It was right that Parliament should take note of that fact and remember the great work that he had done for the health of the people of Scotland—(general cheers)—during the many years that he had been entrusted with the control of their health. The reason that a new medical member had not yet been appointed was simply that the bill for the reorganization of offices in Scotland had not yet received the Royal Assent. As soon as that bill became law the Secretary for Scotland would proceed with the utmost expedition to make the new appointment. He had nothing further to report for the moment in regard to hospitals but the proposals that had been put forward would be considered. He was not able to say that the shortage of hospital beds had been remedied but an improvement was being effected almost constantly, with resulting increased hospital accommodation for the sick people of Scotland. Only a few weeks ago he had inaugurated a new Northern Infirmary at Inverness, where considerably increased medical facilities had been made available for the people in the northern districts. With regard to the report of the Departmental Committee on Maternal Mortality the Board had done its utmost to bring up to date the service in Scotland for pregnant women. The Maternity Homes Bill ensured that there was a service available for 100 per cent of the mothers of Scotland, a thing that could be said of very few other countries. The Board had not succeeded in reducing the very high percentage of deaths from puerperal fever, but it was considering other steps to deal with the matter. The service had been made available, however, and it would do its utmost by administrative action, to secure that further institutional accommodation was made available for women undergoing childbirth.

The vote was agreed to.

National Health Insurance

From the passing of the National Health Insurance Act in 1911 to December 31st 1927 £102,018,000 has been paid in sickness benefit in England and Wales.

On August 2nd Mr. CHAMBERLAIN informed Dr. Salter that the system adopted by the Government actuary to determine the Central Practitioners' Fund was based upon principles which were deemed to be permanent although a report made upon it by an independent actuary to a body representing the insurance practitioners had said that in certain respects the method could not at the moment attain its ultimate form.

On August 3rd Mr. CHAMBERLAIN told Mr. Rhys Davies that he had received representations suggesting that every panel doctor should be compelled to install a telephone to facilitate calls made in urgency by health insurance patients. Mr. Chamberlain added that he had no power to require insurance practitioners to do this.

Small pox

Mr. Broomfield asked Mr. Chamberlain on August 1st whether he knew that a boy aged 11 years, of Chipstead Valley Road, Coulsdon, was vaccinated by the public vaccinator for Coulsdon on June 11th, 1928 and died on June 26th and whether Mr. Chamberlain would cause an investigation to be made into the possible connexion between the vaccination and the inflammation of the brain which caused the boy's death. Mr. CHAMBERLAIN said he was aware of the case. The coroner after inquest and post mortem examination, certified the death to be due to sun stroke.

Medical officers of the Ministry of Health are inquiring into the circumstances associated with the illness of a girl of Werekham, Norfolk who fell ill on the eleventh day after vaccination and died of "sleepy sickness" at Addenbrooke's Hospital, Cambridge, on July 6th. They are also inquiring into the illness of another child in the same district who, in a question put by Mr. Groves on August 3rd was alleged to be a victim of "sleepy sickness" following vaccination. When stating this Mr. CHAMBERLAIN added that two similar cases had occurred at Werekham, but he had no information of any such case at East Werekham.

On August 3rd Mr. CHAMBERLAIN told Mr. Groves that eleven death certificates on which the words "vaccination or vaccine" appeared had been received for the period January 1st to June 30th 1928. On six of these certificates some form of nervous disease was entered. In ten instances death followed closely after vaccination.

An writing Sir Robert Thomas on August 3rd Mr. CHAMBERLAIN said he had received resolutions representing that Poor Law guardians felt apprehension at the increasing tendency among the poorer members of the community to obtain exemption from vaccination. The desirability of withdrawing the present facilities for exemption and of insisting upon the vaccination of infants unless there was some special reason for exemption would be considered in connexion with the report of the Committee on Vaccination.

Medical Inspection of Vagrants—Mr. CHAMBERLAIN replying on July 31st to Dr. Vernon Davies, said that if a vagrant who on entering a casual ward expressed the desire to leave at 6.30 the next morning was not medically inspected on the evening of his arrival he would be examined on the following day and would not be allowed to leave until the examination. He had no precise information on the question whether vagrants who entered the casual ward of an institution which had a resident medical officer attached were medically inspected on the evening of their arrival or on the following morning. He would inquire into any case in which Dr. Davies had reason to believe that the examination was not carried out on the evening of arrival. There were 482 casual wards in England and Wales in regular use. Every ward was inspected at least once a year and more frequently where circumstances required it.

Trypanosomiasis in the British Army—On July 31st Sir L. WORTHINGTON EVANS informed Colonel Hcaage that there had been one case of sleeping sickness (trypanosomiasis) in the British Army between 1923 and 1927. Statistics for the war period were not available. The disease was not notifiable in England and Wales and there were therefore no figures to show the incidence among the civilian population.

Maternal Mortality Rates—On July 30th Mr. CHAMBERLAIN informed Mr. Scurr that full particulars on births and maternal deaths from which maternal mortality rates could be derived together with infantile mortality rates were published in respect of each metropolitan borough in the Registrar General's statistical review. The Minister added a long statistical table showing the expenditure in each of the last five years by each metropolitan borough council on maternity and child welfare services and the Exchequer contribution in each case.

Stabilization of War Pensions—Major TRYON on July 31st told Colonel Clifton Brown that the Government had decided to stabilize war pensions on the cost of living for the standard year 1919. The present rates would not be reduced however much the cost of living might fall. It was the intention of the Government to stabilize the other provisions of the present warrants and in particular those relating to medical treatment and the existing lines of their working for the cases to which they were applicable. He pointed out that those provisions were drawn in 1918 and 1919, during the war and demobilization periods with a particular class of case in view—namely the case for which a special course of treatment of a remedial nature was essential in order to effect a cure or permanent improvement. Provision might become necessary in the future for a different class of case—namely, the case which had reached the stage of needing institutional care and attention rather than a course of remedial treatment. The former class of case would, of course, continue to be provided for on existing lines but other provision would probably have to be made for the latter class of case. Dr. DAWKINS SMITH asked if it was not the case that this concession, however desirable would cost nothing unless the cost of living figure fell below 60. Major TRYON replied that the difference between the new system and the old system was £5,500,000 a year. Mr. F. O. ROBERTS asked the Minister to give a further explanation of what he meant by stabilization of treatment. Major TRYON said that he meant stabilization of the treatment allowances now payable. Mr. ROBERTS asked if that would limit the opportunities for further application to be made for treatment allowances. Major TRYON No, not in any way.

Treatment of Neurasthenic War Pensioners—Major TRYON, in a reply on August 2nd to Mr. Hore Belisha said medical officers of local branches of the Ministry of Pensions were not precluded from giving treatment or making treatment allowances to neurasthenic cases without first referring the matter to headquarters. The exception was in cases recommended for inpatient treatment. In these reference to headquarters was necessary to assure a satisfactory allocation of beds in the special hospitals provided for the various types of neurasthenic cases.

Tuberculosis—There are no funds at the disposal of the Ministry of Health from which financial aid could be given to the Eford colony for tuberculosis cases, Plymouth. A grant has been given to the Preston Hall colony, but that was an exception. Mr. Chamberlain will arrange for one of the medical inspectors of the Ministry of Health to inquire into the increase of tuberculosis among young children in Middlesbrough. He is not aware that the woman assistant medical officer of health in Middlesbrough has stated that the prevalence of tuberculosis among young children in that town is approaching the condition of Vienna after the war.

The Professor of Sanitation and Hygiene, Trinidad—Mr. AMERY, answering Commander Bellairs on August 3rd said the professor of sanitation and hygiene at the Imperial College of Tropical Agriculture, Trinidad maintained close touch with the London School of Hygiene and Tropical Medicine. It was proposed that a close liaison should be established with the Colonial Medical Research Committee and that the duties of the professor should be extended in the light of experience gained in recent years.

Ethyl Petrol—Asked on August 2nd whether he proposed legislation which would prohibit the use of ethyl petrol for cooking and cleaning Mr. CHAMBERLAIN said the terms of contract between the proprietors of the fuel and the retailers were designed to prevent such use. He accepted the opinion of the Government Committee on ethyl petrol that the terms of contract in force safeguarded the interests of the public.

Medical Examination of Employees in Metal Grinding Industries—Sir W. JOYNSON HICKS, in an answer on August 3rd to Mr. W. Thorne stated that no medical test for employment was imposed by the Metal Grinding Industries (Silicosis) Scheme. Workmen

employed by some firms in these industries had been required by their employers to pass a special medical examination some others who failed to pass had been discharged. From July 1st to December 31st there were seven cases under the scheme.

Western Ophthalmic Hospital—Mr CHAMBERLAIN stated on August 3rd that he had no funds at his disposal for making grants in aid of expenditure on building of voluntary hospitals. He had seen reports that a dangerous structure notice had been served in respect of the Western Ophthalmic Hospital Marylebone Road, London.

Notes in Brief

The Ministry of Health's proposals to local authorities to cut down their grants for the supply of milk and nourishment in connexion with maternity and child welfare work will result in a reduction in Exchequer grants this year of about £12,000.

Regulations for the stamping of milk bottles used as measures are under consideration.

Orders have been issued that in future British troops in training are not to place within reach of any road or house smoke generators which have a lacrymatory effect. Complaint was made in the House of Commons about recent use of such apparatus in the Bagshot area.

The Home Secretary is causing inquiries to be made into the ventilation of beet sugar factories. He has no power to control the hours worked by men in these factories.

Mr Chamberlain has no evidence to show that the inhalation of dust from cement works is injurious to health.

In 1927 the ratio of cases of ophthalmia lachrymen per 10,000 troops at home was 2.06 and abroad 0.63 among the civil population in England and Wales in the same year it was 0.41 the total cases at home being 19 military and 1,615 civilian.

Mr Chamberlain stated on August 1st that during the past twelve months the Ministry of Health had not taken nor advised any other department to take any action to prevent the nuisance caused by noisy traffic.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on August 4th the following medical degrees were conferred:

B.M.—T. L. Davies, A. J. Leslie-Spinks.

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University in the subjects and at the institutions indicated:

St Bartholomew's Hospital Medical College—Mr Geoffrey L. Keynes (surgery), Dr A. G. Roxburgh (dermatology), Mr Wilfred Shaw (obstetrics and gynaecology).

St Thomas's Hospital Medical School—Mr John Lowndes (chemistry).

London Hospital Medical College—Dr W. Russell Brain (medicine), **Charity Cross Hospital Medical School**—Dr J. B. Danister (obstetrics and gynaecology).

London School of Medicine for Women—Dr Gertrude Dearnley (gynaecology), Dr Hazel H. O. Gregory (diseases of children), Mrs Barbara Spott (anaesthetics).

University College Hospital Medical School—Dr J. W. McVee (medicine), Dr Wilfred J. Pearson (diseases of children), Mr Bertram Samuel (orthodontics), Mr Julian Taylor (surgery), Dr A. F. Tredgold (psychological medicine).

Kings College Hospital Medical School—Mr Harold O. Edwards and Mr J. B. Hunter (surgery), Dr Wilfrid P. H. Sheldon (diseases of children).

St Mary's Hospital Medical School—Mr R. M. Handfield-Jones (surgery).

London School of Hygiene and Tropical Medicine—Mr V. B. Wigglesworth (medical entomology).

It was reported that Dr H. G. Reeves had, as a matter of urgency, been appointed a member of the Board of Examiners in Physiology at the second examination for medical degree, in place of Professor H. Hartridge, who was unable to do owing to illness.

A grant of £20 from the Thomas Smythe Hughes Medical Research Fund has been made to Ruth Deaneley B.A. B.Sc. to expend on the buying of animals and histological expenses for the purpose of investigations on the experimental histology of the adrenal cortex.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on July 31st when the President Sir Berkeley Almonhan Bt., was in the chair.

Diplomas and Licences

The diploma of Fellowship was granted to Mr Herbert John Seidon who had now complied with the regulations.

Diplomas of Membership were granted to 158 candidates. (The names with the exception of Thelma Shepherd were included in the list published in the report of the Council of the Royal College of Physicians of London printed in our issue of August 4th (p. 225) as were also the names of those receiving the diplomas in Public Health and in Ophthalmic Medicine and Surgery.)

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians to the following:

T. D. Amad, Maud O. Cairney, K. Cathiravelu, G. L. Chadha, S. S. Crooke, C. H. Doyereux, J. P. M. Donnelly, N. M. Dostvalin, Alice M. A. Downing, A. W. Duncan, H. A. Glikes, M. A. El-H Gohar, I. S. Gupta, N. Gupta, M. Jaffer, H. O. Johnson, H. Kalfz, Mary Keith Thompson, J. N. Leitch, R. B. Landeherg, L. J.

McGregor, C. D. Newman, Annie B. Price, E. L. Robert, A. N. Sharma, G. Singh, J. D. S. Thomas, R. F. Tredro, M. K. Tucker, K. H. Utley, Kathleen A. Vernon, P. L. Whig, E. R. Wide.

Licences in dental surgery were granted to A. M. Bennett and H. A. Lewis, who had now complied with the regulations.

Appointments

Mr T. P. Legg was re-elected a member of the Court of Examiners at the expiration of his period of office.

Mr A. B. G. Underwood was re-elected a member of the Board of Examiners at the expiration of his period of office.

Mr N. E. Kelly was elected a member of the Court of the University of Liverpool, in the vacancy occasioned by the death of Mr W. Thelwall Thomas.

Annual Dinner of Fellows and Members

The first annual dinner for Fellows and Members under the trust established by Mr G. Buckton Browne, will take place on Thursday, November 1st, at 7.30 p.m.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates have been approved at the examination indicated:

Primary Fellowship Examination—H. T. Fleming, S. V. Furong.

R. Grainger, T. J. A. McHugh, N. Narasimhan, A. H. Thompson.

Final Fellowship—W. G. Lyons, T. J. Millin.

SCHOOLS OF SURGERY

The following prizes have been awarded for 1927-28—

Junior Anatomy (1) Miss B. M. Dunne, (2) M. King. **Systematic Anatomy** (1) T. Conlon, (2) J. Hampson. **Miss A. J. Dunlevy**. **Surface and Topographical Anatomy** (1) T. F. Quigley, (2) T. Conlon. **Practical Anatomy** (1) T. Conlon, (2) J. Hampson. **Stoney Memorial Gold Medal** T. Conlon. **Physiology** (1) P. D. O'Rourke. **Histology** (1) E. A. Joyce, (2) R. A. M. Montgomerie. **Biologs** (1) G. P. Yenser. (2) P. J. Shields. **J. O'Hanrahan**. **Medica Medica** (1) J. Hampson. (2) M. J. O'Callaghan. **Forensic Medicine** (1) Miss A. J. Dunlevy. (2) I. McLachlan. **Medicine** (1) P. Daly. **Operative Surgery** Gold Medal 1. Daly. **Midwifery** (1) J. E. Lewis.

CONJOINT BOARD IN IRELAND

The following candidates have been approved at the examination indicated:

Final Professional—T. B. Creamer, Eileen Cusson, N. Dinnphy.

R. A. Forde, J. Gangan, W. G. Greene, A. E. Lee, J. L. Maslin.

N. G. Mattock, F. J. A. Murra, H. Rubinstein.

D. P. H.—V. F. M. Lee.

Medical News.

The Royal College of Physicians of London will be closed for the summer vacation from Monday, August 13th, to Saturday, September 15th, both days inclusive.

The annual dinner of past and present students of St Mary's Hospital will be held on Friday, October 5th, at 7.30 o'clock at the Trocadero Restaurant, with Dr E. G. Moon in the chair. The honorary secretary is Dr A. Hope Gosse.

A course of lectures and demonstrations on clinical practice and hospital administration for the diploma in public health will be given at the North Eastern Hospital, St Ann's Road, Tottenham, N.15, by Dr F. H. Thomson, medical superintendent on Mondays and Wednesdays at 4.45 p.m., and alternate Saturdays at 11 a.m., beginning Monday, October 1st. The fees for the course, which comply with the requirements under the revised regulations of the General Medical Council, is £4 4s., and for a course under the old regulations £3 3s. The fee should be paid in advance to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C.4.

The Fellowship of Medicine and Post Graduate Medical Association announces that a fortnight's afternoon course at the Infants Hospital starts on Monday, August 13th, while on August 27th at Queen Mary's Hospital will begin a two weeks course in medicine, surgery, and the specialties. The mornings will be given to special lectures and demonstrations, and in the afternoons there will be a choice of operations or of medical, surgical or special clinics, followed after tea by a lecture. Special courses arranged for September comprise the following: psychological medicine at Bethlem Royal Hospital, medicine, surgery, and specialties at the Westminster Hospital, diseases of children at the Queen's Hospital, electrotherapy at the Royal Free Hospital, ophthalmology at the Royal Eye Hospital, and orthopaedics at the Royal National Orthopaedic Hospital. In October weekly clinical demonstrations will be resumed. There will also be a special course at the Wellcome Museum of Medical Science and a series of lectures on gynaecology, children's diseases, and minor surgery. Detailed syllabuses and other information may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

ARRANGEMENTS have been made for the exhibition at post offices of lists of the names and addresses of infant welfare centres and ante-natal clinics. Postmasters at Crown post offices have been instructed to do so and sub-postmasters at offices where postal work is performed under contract have been requested to co-operate. The Ministry of Health therefore suggests (in Circular 911) the local authorities should prepare such lists and arrange for their exhibition. Nothing beyond the names and addresses of centres and clinics should be given in the list which should be printed on cardboard not exceeding foolscap size.

In the recent special distribution of the Wells legacies, King Edward's Hospital Fund for London set aside a grant of £10,000 towards the building fund of the King George Hospital, subject to certain conditions, and the King's Fund has been informed that an appeal will shortly be made for public support for the establishment of the hospital. The scheme submitted to the King's Fund contemplates the provision of additional hospital accommodation for the parts of Essex immediately to the east of London, including the area in which this is particularly needed owing to housing development since the war. The King's Fund proposes to summon a conference with a view to facilitating the execution of the scheme.

A COMBINED medical, electrical, and pharmaceutical congress and exhibition will be held in October in Mexico City, under the auspices of the President of the Republic, the Mexico Medical Association, National University, Health Department, and the Mexican Society of Electro-Radiology. Further information may be obtained from the managing director of the exhibition, Apartado 982, Mexico, D.F.

THE late Inspector General Henry Hadlow, R.N., who died in November last, aged 92, has bequeathed £10,000 stock to Epsom College for the creation of a pension fund for medical men and their widows, £8,560 to the Royal Portsmouth Hospital, and £100 to the Portsmouth Eye and Ear Hospital.

THE eighth Congress of the German Pharmacological Society will be held at Hamburg, under the presidency of Professor E. P. Plotz of Vienna, from September 12th to 15th. September 13th will be devoted to discussions on the work of the heart and vessels in honour of William Harvey, when papers will be read by Liljestrand of Stockholm, Jarisch of Innsbruck, Straub of Göttingen, Anrop of Cambridge, and Mansfeld of Pécs. On the 14th papers will be read on modern industrial intoxications by Flury of Würzburg and Zangger of Zürich, and on the 15th Bürger of Edinburgh will read a paper on ergot bases. Further information can be obtained from Professor H. Wieland, Pharmakologisches Institut, Heidelberg.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the British Medical Journal must communicate with the Editorial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the Journal, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the British Medical Journal are MUSFUL 9561, 9562, 9563, and 9564 (informal exchange four lines).

THE TELEGRAPHIC ADDRESSES are EDITOR of the British Medical Journal, Antology Westcott London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) Articulate Westcott London.

MEDICAL SECRETARY Medicorum Westcott London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Basillus Dublin* telephone 62550 Dublin) and of the Scottish Office, 7 Drumhaugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS

DRESSING FOR FISTULA

DR A. V. RUSSELL (Innisfree) writes: Has "R.T." who asked for suggestions for a suitable dressing for a patient with a small intestine fistula tried iodine? Colloidal kaolin worked into a stiff paste with the addition of glycerin and applied to the inflamed skin round such a fistula has, to my knowledge, acted like a charm. This dressing acts by adsorption of the digestive enzymes.

THYROID EXTRACT FOR ANEURYSM

"M.D." would be glad to hear of any experience of thyroid gland extract in the treatment of thoracic aneurysm—used with the object of lowering blood pressure and assisting blood coagulation.

CORNS

"J. J. K." writes in reply to "H. A. A." (July 14th p. 85) to suggest the following method of relief for corns on the soles of the feet: Wear an inner cork sole in the shoes and cut out from this a shallow excavation with shelving edges immediately below the corn. The writer says that he has found this device combined with the application of a saturated solution of salicylic acid in collodion, most successful.

INCOME TAX

Falling Income

"R. E. L." states that his income for the year 1928 will certainly be less than the amount estimated on which he paid the tax in 1927. Can he claim any refund?

. The inquiry is not entirely clear. The tax recently paid is presumably the second instalment of the tax assessed for the year to April 5th, 1928, the correct basis for which in normal circumstances would be the amount of the income of the year 1926—that is, the previous year to the year 1927–28. If the tax has been assessed on that basis and not on any 'estimated' amount then no revision of that assessment can be claimed. Similarly, as regards the year ending April 5th, 1929, the assessment should be made on the amount of the income of 1927 and remains unaffected by any increase or decrease in 1928. It should be borne in mind that income tax is paid for any particular financial year on an artificial statutory basis, but it is paid for that year and the tax is not strictly a deferred tax on the income of the basis year. The above observations do not necessarily apply to the first or final years of the taxpayer's possession of the partnership share or practice.

Depreciation of Car Private Use

"H. C. P." explains that his car is to some extent used for pleasure, and the authorities have claimed to restrict the depreciation allowance accordingly.

. The claim cannot be refuted. If say 10 per cent of the car's mileage is for private purposes then 10 per cent of the whole cost including depreciation, cannot properly be claimed against the professional earnings. We are hardly in a position to say whether it is now the general practice to knock off this depreciation, but it seems at least to be not uncommon.

LETTERS, NOTES, ETC.

FRACTURE OF CERVICAL VERTEBRÆ

DR K. T. RAMOJIANPANI (Hyderabad India) writes: Sir William Wheeler's case of fracture of the cervical vertebrae reported in the *Journal* of March 31st p. 553 prompts me to record a similar case in which a necropsy was performed at the Civil Hospital, Hyderabad, on May 19th. A dead body was sent with the history that death had occurred in the course of a struggle in which the man had been forcibly thrown against the ground in such a way that the head was bent forwards causing hyperflexion of the neck. No information is available as to what happened to the man before death beyond a verbal statement that he had asked for drinking water and that he could not move his arms indicating that he was conscious and had brachial palsy (presumably also paraplegia) after the injury—a feature reported also in Sir William Wheeler's case. On opening up the vertebral column a spiral fracture of the fifth and sixth cervical vertebrae similar to that found in Sir William Wheeler's case was seen. The disc between the two vertebrae having been torn open. Some small fragments of bone were detached and were found in the soft structures close to the site of injury, but none was pressing upon the cord which appeared intact. On making a transverse section of the cord and displacing it upwards no projection was felt underneath it indicating any dislocation of the vertebrae. This case seems to support the reasonable theory of Sir William Wheeler—that the trauma to the cord on such occasions is analogous to that produced by overstretching of the brachial plexus or of the muscular spinal nerve innervation as in both cases the lesion was situated below the site of emergence of the phrenic nerve (third vertebra) and there was no apparent compression of the cord though death ensued in both cases. My thanks are due to Major M. J. Holgate, I.M.S., for permission to publish this note.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 38, 39, 42, 43, and 44 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 102.

Observations ON CHRONIC SPLENOMEGALY IN CHILDHOOD DIAGNOSIS AND TREATMENT*

BY

ROBERT HUTCHISON, M.D., F.R.C.P.,

Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond Street

BEFORE proceeding to the differential diagnosis of the various splenomegalies of childhood, it is advisable to make sure that the abdominal tumour in question really is an enlarged spleen. Usually this is easy enough, but sometimes one is in doubt, especially as to the possibility that the tumour may be an enlarged left kidney or suprarenal. Sometimes the ordinary diagnostic criteria—that a large spleen does not extend back into the loin, that it has a sharp edge with a notch, that it crosses the middle line below the umbilicus, that the fingers cannot be passed between the tumour and the ribs, that the descending colon does not lie in front of it—all fail, and in that case it is important to remember that dullness extending above the level of the ninth rib in the mid axillary line is in favour of the tumour being splenic. An x-ray examination, with pycnography if necessary, may help in the differentiation. I would only repeat that the difficulty of telling a splenic from a renal tumour is sometimes a real one, and that the methods of distinguishing them are worth discussion.

Having settled that the tumour is an enlarged spleen, it is necessary, before proceeding farther, to have some sort of classification of the different varieties of splenomegaly met with in childhood. The only satisfactory classification would be an etiological one, but of that our present knowledge does not allow, and I therefore propose, for purposes of discussion, to consider the subject under certain broad groups.

1 Tumours (Cysts, Ater Cysts, Abscesses, etc.)

These are very rare, and for practical purposes undiagnosable. If diagnosed, the proper treatment, of course, would be surgical.

2 Chronic Infections

Of these we have to consider tuberculosis, syphilis, lymphadenoma, and chronic sepsis.

In chronic tuberculosis splenomegaly is not likely to be the "presenting" sign, although in the acuter forms of tuberculosis in young infants enlargement of the spleen is very common. Cases are described, however, though I do not remember to have seen one myself, in which massive caseating tuberculosis leads to considerable splenomegaly. The spleen in such cases may be tender, and polycythaemia and some degree of cyanosis are said sometimes to be present. There will often, of course, be less conspicuous tuberculous lesions elsewhere. The proper treatment is splenectomy.

The relation of congenital syphilis to splenomegaly in childhood is very important, but I would suggest, for purposes of discussion, that its frequency as a factor in causing the condition tends to be exaggerated. After all, inherited syphilis is a comparatively rare disease, and so we may say that, although syphilis certainly very often leads to splenomegaly, yet not many cases of splenomegaly are due to syphilis. It is in infancy that a syphilitic enlargement of the spleen is most likely to be met with, but there is reason to believe that in later childhood—say, between the ages of 5 and 7—splenomegaly may be the only sign of a syphilitic taint, and it appears again about the age of puberty in association with syphilitic cirrhosis of the liver. In the pre-Wassermann days the tendency was to ascribe every splenomegaly of doubtful origin to syphilis, but since the introduction of that test I have been impressed by the frequency with which it is found to be negative in these circumstances. I am aware that in some undoubtedly syphilitic cases—in syphilitic cirrhosis, for instance—the

Wassermann reaction may be negative, and we might well discuss what degree of confidence we can place in it as a criterion of the presence or absence of a syphilitic taint. I would only point out that it is, after all, the only positive test we have in a case in which unmistakable objective signs of the disease are wanting, and if we are not to be able to trust it the whole question of the relation of syphilis to splenomegalies of obscure origin in childhood goes back into the melting-pot. It is all the more important that we should have some trustworthy test for the presence of syphilis, inasmuch as it has been suggested by Dr. Parkes Weber and others that an inherited taint may form a basis on which enlargement of the spleen—though not primarily due to syphilis—may develop more easily, or in a more exaggerated degree than it does in a child whose heredity is not thus burdened. Although this view seems to me rather speculative, it would be of interest to have opinions upon it.

Where syphilis is believed to be the cause of a splenomegaly, vigorous antisyphilitic treatment must, of course, be adopted. In some cases, however, the changes in the spleen may have proceeded so far that they are unaffected by any form of drug treatment, and in that case splenectomy may be justifiable.

Lymphadenoma as a cause of enlargement of the spleen, without there being evidence of the disease in the glands, must be very rare. For my own part, I have never met with an instance of it, though cases have been described by others,¹ and I do not see how it can be diagnosed with certainty. If diagnosed, the appropriate treatment would be the application of x-rays to the tumour.

Chronic sepsis has been put forward as a cause of splenomegaly, as of most other things. Dr. Gordon Ward,² for instance, regards it as of considerable importance, though I think on rather insufficient grounds. That splenomegaly may be the presenting sign in cases of very chronic infective endocarditis (endocarditis lenta) is certain, but I doubt if cases of this very chronic type are ever met with in childhood, and of "intestinal sepsis" as a cause of enlarged spleen we know nothing.

3 Tropical Splenomegalies

Chronic protozoal infections, as in malaria and kala-azar, may cause great enlargement of the spleen in children, but as the diagnosis and treatment of these diseases is the same as in adults we need not discuss them.

4 Splenomegaly in Metabolic Diseases

We have here chiefly to discuss the part played by rickets. This has been almost as much disputed as the role of syphilis in producing splenomegaly, and I believe fully as much exaggerated. That severe rickets tends to be accompanied by some degree of enlargement of the spleen is undeniable, though in some cases the organ is not so much enlarged as pushed down by deformity of the ribs; but I would suggest, for purposes of discussion, that rickets alone is not an important factor in the production of splenomegaly, especially nowadays. The same may be said, with even greater truth, of wax disease, which we need rarely think of when the nature of an enlarged spleen is under discussion.

5 Gaucher's Disease

Gaucher's disease should, I suppose, now be included under the metabolic disorders associated with splenomegaly. It is rare, though probably not so rare as is believed, and is to be diagnosed by its familial, though not hereditary, incidence, and, above all, by the demonstration of the characteristic endothelial cells in the product of a splenic puncture.³ Opinions as to the value of splenectomy in the Gaucher cases are divergent. The operation cannot certainly be regarded as a cure, seeing that the disease is one which is not confined to the spleen, but affects the whole reticulo-endothelial system throughout the body. If the splenic tumour is causing local discomfort, however, its removal would appear to be justified.

6 Splenomegaly in Diseases of the Blood

We have here to consider the leukaemias, splenic anaemia of infancy (anaemia pseudo-leukaemia infantum of von Jaksch), acholuric jaundice, purpura, and erythraemia.

Made in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Cardiff, 1928.

The *leukaemia* we may dismiss in a word. In childhood they are almost always acute, and therefore not a cause of chronic splenomegaly. I have only once seen a case of chronic myeloid leukaemia in a child—a boy of 12—and for practical purposes leukaemia as the cause of a chronically enlarged spleen in childhood need not be considered. If suspected, a blood count would at once establish the diagnosis.

The *splenic anaemia of infancy* is in an altogether different category. It used to be relatively common, and when I was giving the Goulstonian Lectures twenty-five years ago I had no difficulty in collecting notes of a large number of cases, all of which had been under my own observation. In recent years, however, it has become rare, and I have not seen a typical case now for a long time. I do not propose to discuss the nature of this disease, and whether it is merely the result of a haemopoietic reaction to various debilitating influences in childhood, or whether it is—as I at least hold—a disease *sui generis*. For our present purpose it is sufficient to point out that it should not be diagnosed after the age of 3, although it is true that the enlarged spleen may persist beyond that age, when the anaemia has passed off, before gradually disappearing. In that case, however, there should be a clear history of the disease in the earlier years. The blood picture in the acute phase is characteristic.

In considering the treatment of this form it is to be remembered that the disease tends to spontaneous recovery in the great majority of cases, given suitable hygienic measures. I do not myself consider that splenectomy is ever called for in it, as the operation must be highly dangerous in the severe forms and is unnecessary in the milder. Some successful cases have, however, been reported by Ashby and Southam,⁴ but I think it probable that these would have recovered without operation. Whether x-ray treatment is of any use I am not sure. In the few cases in which I have tried it the results have been disappointing, but others⁵ have been more fortunate. At least, it cannot do any harm.

I need not say much about the splenomegaly of *acholuric jaundice*, it is now well recognized as a not uncommon occurrence, and the diagnosis can be established with certainty from the characteristic increased fragility of the red cells. There is also no doubt that splenectomy is the only effective form of treatment.

In *purpura*—even in the chronic forms—splenomegaly is not likely to be the presenting sign, and I only mention it here because in that variety of the disease in which the platelets are greatly diminished removal of the spleen is now generally agreed to be very beneficial.

I doubt whether true *erythraemia* (Osler-Vaquez disease) is ever a cause of chronic splenomegaly in childhood, but it is interesting to note that polycythaemia is sometimes a feature in cases of syphilitic splenomegaly.⁶

7 Splenomegaly Associated with Cirrhosis of the Liver

We now come to that interesting group of cases in which an enlarged spleen is associated with cirrhosis of the liver. Three forms of cirrhosis with splenomegaly—excluding for the moment Banti's disease—may be distinguished.

(a) *Idiopathic Non-alcoholic Progressive Cirrhosis* (Parkes Weber)⁷—This is a cirrhosis of unknown cause, which resembles the ordinary portal cirrhosis of adults, runs a fairly rapid course, and often terminates in haematemesis. The spleen is always enlarged to some degree, but in certain of the cases is so conspicuous and early a feature as to be the "presenting" sign, and these have been spoken of as cases of "splenomegalic cirrhosis," or cirrhosis with "splenic predominance." Their diagnosis from Banti's disease is not easy, and will be considered later, and whether or not they are suitable cases for splenectomy demands discussion. Some writers—Thursfield⁸ for example—maintain that the operation in these cases is almost invariably fatal, but I am not at all sure that this is true. In the following case, for instance, if as I believe it must be included in this group, splenectomy appeared to effect a cure.

The patient was a boy aged 12 who was admitted for bleeding from the gums with a history of always having bruised easily. His spleen was enlarged down to the umbilicus and the liver

was easily palpable. The red cells numbered $4\frac{1}{2}$ million with 70 per cent of haemoglobin, and the white cells 1,600. The Wassermann reaction was negative, both in the patient and in his mother. Four months later he was readmitted with ascites. The spleen was removed and at the operation the liver was found to be cirrhotic. Twelve years later he was in excellent health.

The question of splenectomy in these cases is, I repeat, one for discussion.

(b) *Syphilitic Cirrhosis with Splenomegaly*—These cases are met with in later childhood about the time when interstitial keratitis and the other signs of "late syphilis" manifest themselves, and I have already said that there is reason to believe that they do not always give a positive Wassermann reaction, and that, if antisyphilitic treatment fails, removal of the spleen may be justified.

(c) *Splenomegaly with Biliary Cirrhosis*—These are the cases described by Gilbert and Fournier,⁹ and are believed to be the form which Hanot's cirrhosis takes in the child. They are said to be characterized by the presence of a much enlarged spleen, recurring jaundice, finger-clubbing, and impairment of growth, but without ascites. Now I am very sceptical as to the existence of Hanot's cirrhosis at all, and still more sceptical as to the occurrence of such cases in the child. I once thought I had such a case—I have described it elsewhere¹⁰—but it proved *post mortem* to be a case of partial obliteration of the bile ducts, presumably of congenital origin. I shall, however, be interested to hear the opinions of others on the subject.

8 Splenomegaly the Result of Splenic Thrombosis

That thrombosis of the splenic vein could cause enlargement of the spleen was denied by Osler,¹¹ yet there seems to be no doubt that it does happen. I have myself seen two cases in the adult in which this was proved at the necropsy to be the cause, and a case of it has been published by Parkes Weber.¹² Wallgren,¹³ in an important paper, has drawn attention to it as a cause of splenomegaly in children, and believes that it is commoner than is supposed, but that it has hitherto been confused with Banti's disease. He describes the leading features of the syndrome as splenomegaly, anaemia with leucopenia, and slight ascites. Sooner or later haematemesis sets in, and after a bleeding the volume of the spleen *shrinks*—thus, he believes, does not happen after haematemesis in Banti's disease or in cirrhosis—and at the same time a temporary leucocytosis appears. The liver in all of his cases coming to necropsy was found to be normal.

He is of opinion that the thrombosis of the splenic vein is the result of trauma or of an "infection," and that it leads to engorgement of the spleen and dilatation of the veins at the lower end of the oesophagus, rupture of one of which causes the haematemesis, with temporary subsidence of the splenic tumour. Wallgren believes that the prognosis in these cases is bad unless splenectomy is performed.

I believe that the following case may be regarded as one of splenic thrombosis.

The patient was a boy aged 5. Two years before admission he vomited a teacupful of blood, and this was repeated one year later, and again one week before his admission to hospital. He had had no other illness except whooping-cough when he was 4. He was a pallid weakly but not ill-nourished child, with a "buscuit" tinge of skin. The spleen was palpable and the liver extended one inch below the costal margin. There were a few small palpable glands in the axillae. A blood count showed red cells 1,160,000, white cells 5,620, haemoglobin below 30 per cent. A few normoblasts were present. The differential count was normal. The Wassermann reaction was negative. Ten days after admission he vomited an ounce of bright red blood, and at the same time his temperature rose to 103° F. The white cells were at this time 12,000. There is no note as to the effect of the haemorrhage on the size of the spleen. He was transfused but with only temporary benefit and died two weeks after his admission.

At necropsy the spleen was four times the normal size, firm and tough. There was *ante mortem* thrombosis of the splenic vein and also recent clotting in some of the mesenteric veins. The liver was large pale not cirrhotic. There were a few small varices at the lower end of the oesophagus.

9 Splenic Anaemia of Adult Type and Banti's Disease

It will be generally agreed, I think, that "splenic anaemia" and "Banti's disease" are to some extent diagnostic "rag bags" into which are thrown all the cases of enlarged spleen that cannot be placed in any other category. None the less it will be admitted that cases to

which these terms are applicable have a real existence in the adult, and the question for us to-day is whether they are also met with in childhood. Now, seeing that the splenic anaemia of adults is of its essence a very prolonged disease, the final stage of which, when cirrhosis of the liver has supervened (so-called Banti's disease) is only reached after some years, it follows that Banti's disease at least is not likely to be met with whilst the patient is still in childhood. In spite of this I think the diagnosis "Banti's disease" is sometimes justified in childhood, as in the following case:

A boy of 12 was known to have had an enlarged spleen for five years. The liver was not enlarged. The blood count showed 2,750,000 red cells, 45.1 per cent of haemoglobin, and 3,400 white cells. Wassermann test negative. Haematemesis supervened after which the spleen was decidedly smaller for some days. There was no leucocytosis during or after the haemorrhage. Splenectomy was performed and at the operation the liver seemed to be the seat of early cirrhosis. His subsequent history is unknown.

The difficulty, of course, is to distinguish such cases from those of idiopathic cirrhosis "with splenic predominance," already referred to. It can only be done if the history shows that the spleen was enlarged for some years (as in the above case) before signs of cirrhosis supervened, for the cases of idiopathic cirrhosis seem to run their whole course in a comparatively short space of time. There is little doubt, too, that cases of splenomegaly due to splenic thrombosis must often have been included under the term "splenic anaemia or Banti's disease," and so, probably, have some syphilitic cases and some of acholuric jaundice.

It is sometimes asserted that the presence of leucopenia puts a case in the category of splenic anaemia rather than of idiopathic cirrhosis, but to this I cannot agree. In the case of idiopathic cirrhosis with splenic predominance which was described earlier in this paper, for instance, leucopenia was present, and my own view is that leucopenia tends to be a feature of most chronic splenomegalies, no matter of what origin, and that little diagnostic value can be assigned to it.

The treatment for splenic anaemia of the adult type, we should all agree, is splenectomy, but whether the operation is worth doing after cirrhosis has supervened—that is, in Banti's disease—is a matter for consideration.

In conclusion, I would suggest as the most important points for us to discuss: (1) the part played by syphilis and rickets in the production of chronic splenomegaly, (2) the nature of idiopathic cirrhosis with "splenic predominance" and its differentiation from Banti's disease, (3) the existence or otherwise of biliary cirrhosis with splenomegaly, (4) the frequency of splenic thrombosis as a cause of enlarged spleen and its diagnosis from other forms of splenomegaly, (5) the occurrence of cases of splenic anaemia of the adult type and its sequel, Banti's disease, in childhood.

As regards treatment, debate must chiefly centre round the question of splenectomy. As to this, I would agree with Dr. Leonard Parsons¹⁴ that the cases suitable for this operation are those which show a negative Wassermann reaction, no enlargement of lymphatic glands, and no characteristic leucocytic picture, but in which there is some degree of anaemia, associated with (1) leucopenia, or (2) increased fragility of the red cells, or (3) haematemesis. There may be difference of opinion, however, as to the advisability of removing the spleen in Gaucher's disease and in cases with cirrhosis of the liver, whether of the idiopathic or Banti variety, even although these fall within the limits of the above criteria.

AUTOTOXAEMIA AS A FACTOR IN THE CAUSATION OF PSYCHOSES*

BY

PROFESSOR W. WEYGANDT, M.D.,
Hamburg

In psychiatry, as in other spheres of medical science, the history of medicine unveils precursors of many a modern theory. The modern fever therapeutics of psychoses recall memories as far back as Hippocrates and Galenus.

In the course of the past century a great change has taken place in the doctrine of the cause of psychoses. Formerly the psychic cause was represented as the only, or at least the most important, one. As late as 1827 Henroth disputed the fact that fever might be a cause of mental derangement, he emphasized that even in the case of alcoholism the moral origin of all mental disorders could be recognized, and that even in the case of injuries to the head the spiritual life must not be forgotten as a cause.

With the advances of normal and pathological anatomy of the central nervous system, however, the doctrine became more and more firmly settled that mental derangements were cerebral diseases, and that a morbid influence of the brain represents the cause of mental disorders. But the external causes were frequently overestimated. Forty years ago the cause of paralysis was regarded as lying in sexual excesses, overexertion, congestion, injuries to the skull, overheating of the skull, long-enduring shocks, alcoholism, becoming prematurely aged, the climacterics, interruptions or derangements in menstruation, together with certain psychical influences, such as excitement or grief.

Very gradually the doctrine of syphilis being the cause of paralysis opened up new paths of research, and its correctness was finally proved in 1911 by Noguchi tracing the *Spirochaete pallida* in the brain.

As early as 1889 Kraepelin taught in connexion with paralysis that numerous symptoms must be regarded as a direct consequence of the degeneration of certain trophic nerve tracts. In 1896 he described dementia praecox and general paralysis as metabolic diseases.

The later doctrine was accepted, but for all that derangement of the digestive processes is of material importance among the symptoms of paralysis. In this connexion syphilis of the organs must also be mentioned, as well as an increased tendency of the bones to fracture. As to the pathogeny, it is assumed by numerous authors that not only are the symptoms caused directly by the spirochaete, but that a number of them may also be caused by toxic agents produced by the spirochaetes. I regard the lipomatosis that frequently occurs in advanced stages of paralysis as a secondary metabolic derangement, the region of the hypophysis being disturbed by hydrocephalus internus, and abnormal adiposity being thus induced.

The doctrine that dementia praecox is a metabolic disease or auto-intoxication was based on corporeal symptoms and relations—for example, on changes in the reflexes, mechanical excitability of the facial nerve, mechanical excitability of the muscles, dermatography, a peculiar change in the skin, and possibly, too, on disorders in the thyroid glands, and the relations as regards puberty, menstruation, pregnancy, etc. Kraepelin also called attention to an hereditary disposition in 70 per cent of the cases, and also to inherent symptoms of degeneration.

The realization by a large number of alienists that an endogenous cause of the disease must be assumed, above all the study of nerve disorders based upon disease in the blood glands or the glands of internal secretion, has induced an intensive investigation of these factors for decades past. This biological observation and investigation of mental derangements is the more important because cerebral anatomy has not fulfilled the great hopes that were entertained in regard to it. Psychology, too, has not led to very satisfying results, either as regards experimental study or psycho-analysis.

* A paper read in opening a discussion in the Section of Mental Diseases and Neurology of the Annual Meeting of the British Medical Association, Cardiff, 1928.

If the clinician wishes to investigate the nature of character of a mentally changed patient he must undertake not only the usual clinical psychological investigation, but also a detailed neurological examination, he must determine all the hereditary factors, and, as far as possible, carry out a microscopical test of the blood, liquid components, and other materials, and even of an extirpated particle of the brain cortex.

A series of biochemical tests are also necessary in order that the effect of external deleterious principles, and also the endogenous deviations in the digestive processes, may be determined. An endless number of investigations have been carried out, the results of which are but to a small extent of lasting value.

Among the clinical autotoxaemic groups I will first discuss the forms of retarded evolution on the basis of endocrine metabolism. In these groups are comprised several forms of unglandular disorder, the pluriglandular disorders, and, as a group by itself, Mongoloid degeneration. The blood glands are well known to be vegetative organs which are governed by vegetative nerves and influence the excitability of the vegetative system by their hormones. They have mutual relations of co-ordination, promotion, and retardation.

The function of the thyroid gland may be disturbed in early youth, or by a local disease such as inflammation, tumour, tuberculosis, etc., or by operative intervention. The consequences are always the same: retardation of bone growth and of sexual evolution, degeneration of skin such as myxoedema and loss of hair, as well as mental retardation and stupefaction. Complete loss of the thyroid gland results in disturbed function of several organs, such as the sexual glands, the kidneys, the liver, and the adrenal system: the fermenting processes are enfeebled, and also the capacity to produce immune bodies. Albumin metabolism is gravely disturbed, and finally death ensues. These consequences can always be confirmed by experiments on animals. Thyroidectomized animals grow very slowly and their skin degenerates. Without a doubt their intelligence and vivacity are also enfeebled, as I have proved by experiments on goats and pigs. An abnormal function of the thyroid gland can also be proved by Abderhalden's decomposition reaction. That psychical alteration exists was proved by the English Myxoedema Committee—apathy, stupor, and insomnia in 87 per cent, illusions in 18 per cent, hallucinations in 16 per cent, and psychoses in 16 per cent. By removal of the thyroid gland the basal and albumin metabolism are lowered and the tendency to sugar rises.

The possibility of treatment is, theoretically and practically, very important in hypothyroidism. Freshly made preparations of the thyroid gland, liquid or dry, and administered by the mouth or by injection, cause the symptoms to disappear. Good results are obtained in sporadic myxoedema, in cachexia thyreopriva, and in endemic cretinism. A little iodide salt—a few milligrams every week—is also effective in endemic cretinism. Purification of the drinking water is an aid in eradicating this condition, which is on the decline in many countries. Very few cases now occur in southern Germany, and instances continue to grow less frequent in Switzerland, Austria, and in northern Italy.

The case is very different in hyperthyroidism or Graves's disease, with its symptoms of irritability, restlessness, excitement, tachycardia, sweating, tremor, and also exophthalmos. According to Abderhalden the decomposition reaction in Graves's disease can also be shown. In treatment surgical removal of part of the gland is very important but also thymus and ovarian preparations can be employed as well as small quantities of iodides.

The parathyroids or epithelial bodies form ferments which influence the calcium metabolism. According to Loeb the quotient $\frac{ClNa}{ClCa}$ is of importance in the function of the nervous system. After surgical removal of the parathyroid glands there follows an increase in nervous excitability. Certainly diminished function of the parathyroids and probably an effusion of blood into the parathyroid bodies sometimes due to asphyxia at birth, is the cause of tetany and also of spasmiophilia.

The pituitary gland has its interest for neurologists and

also for psychiatrists. There is no doubt that the anterior or glandular part of the pituitary body, either as the result of disease or diminished function, causes a retardation of the skeletal growth, while its over activity results in the production of excessive growth in youth as the result of augmentation of the acidophil cells, and in later life acromegaly develops. The action of the pars intermedia and the pars posterior (or pars nervosa) is more difficult to define. A ferment derived from this part influences the blood pressure and unstriated muscles, and its action is also discernible in cases of polyuria and glycosuria.

With regard to the localization of dystrophia adiposogenitalis opinions differ. Some authors consider that this depends on the pars anterior or, as Biedl thinks, on the pars intermedia. According to B. Fischer and to Cushing this condition is caused by disorder of the pars posterior. Other authorities assume morbid processes in the region of the hypophysis, in the infundibulum cerebri, or in the regio subthalamica. As the basis of such degeneration one may consider a birth deformity or the pressure of a tumour or hydrocephalus.

A more recently recognized condition is cachexia hypophyseopriva, or Simmond's disease, which causes bodily decay and death through non-function of this gland, probably of the pars anterior. Sometimes a hypodystrophia can lead to cachexia through progressive pressure.

It is important to realize that gigantism in youth and acromegaly can be associated with idiocy and a primary disorder of the cortex cerebri be assumed.

Further, dystrophia adiposogenitalis is often associated with idiocy and imbecility. This form of feeble-mindedness, as I have shown, is often connected with a cheerful mood and motor unrest, which is in odd contrast with the plump and corpulent figure. In rarer cases, also, abstraction, hallucinations, loquacity, depression, and sleeplessness are described.

I shall shortly touch upon the rare cases of premature puberty in disorders of the epiphysis cerebri, mostly caused by tumours (principally teratomata), whereby the physiological retardation caused by this gland disappears. According to A. Frölich "apinealism" leads to cachexia, hypopinealism to sexual hypertrophy and premature puberty, but hyperpinealism to general obesity.

Hypofunction of the sexual glands is of importance in relation to physical constitution and neurology, but less so to psychiatry. I have mentioned the retardation of sexual glands in myxoedema and cretinism, and the relations of these to dementia praecox I shall consider later.

The thymus has a relation also to psychical evolution. In the condition of status thymico-lymphaticus in its different forms there is psychically some infantilism—a dependent, anxious, feeble, and dreamy character. Also to be remembered is the persistence of the thymus in megalencephalia with feeble-mindedness.

Klose has recovered thymus in young dogs by operation, the animals became fat, ceased to grow, showed clumsy movements, and were easily fatigued. The reflexes were first increased, then decreased, and the electrical excitability of the muscles was augmented, as in tetany. The animals appeared stupid, tried to eat wood and stones, became dirty in their habits, and finally died. Whereas the functioning thymus gland lessens the phosphoric acid and nucleic acid, this is not so after thymectomy, the organism is overburdened with acid, the brain containing much colloid and becoming swollen.

Heinrich Vogt described a case of thymic idiocy: a 17-year-old dwarf, stupid, with feeble, pulpy muscles and weak, elastic bones, the hands trebled, the reflexes were exaggerated, growth of the sexual organs was retarded, and the skin flabby. Later the bones became fragile. Occasionally fits of tremulousness appeared.

The suprarenal cortex and medulla are very important in relation to the nervous system, but less so to psychiatry. In fish of lower species (sharks and rays) the cortex and medulla are separate glands.

The cortex is the more important structure constituting an autonomic central organ for certain parts of the sympathetic nervous system. It absorbs lipoids and provides material which is converted into adrenalin in the medulla.

The medulla, consisting of nerve-endings, nerve cells, and

chromaffin cells, forms adrenaline. The medulla also influences the breaking up of carbohydrates in the liver.

Adenoma of the cortex causes hyperfunction and pre-natal puberty, while hypofunction causes retardation of growth. In Addison's disease, dependent upon disorder of the suprarenal gland, headache, depression, fatigue, excitability, sleeplessness, and feeble memory appear. No doubt both portions of the suprarenal gland are concerned, but it is principally the chromaffin tissue which is affected.

Dysgenitalism can be congenital or caused by illness or operation, as in the popular custom of the Scops in Russia. Prolongation of the long bones is present in young castrated peoples and also in some cases of juvenile syphilis. Castrated subjects show psychical infantilism, but not actual feeble-mindedness.

Disorders of the pancreas can retard growth in youth. Byrom Bramwell described a case of infantilism of this nature in a lad aged 18, who was no more developed than a boy of 11 years. Fat digestion was disturbed, phosphoric acid in the urine became less on milk diet, and the iodide reaction was absent, when iodine salt in gelatin capsules was taken, since the capsules were not dissolved in pancreas juice. These symptoms disappeared after treatment with pancreatic extract, and physical development was speedily resumed. Mental development was in no way affected.

Often differences are made between uniglandular and pluriglandular and also multiglandular disorders. Strictly speaking, no glandular disorder affects one gland alone, for after the loss of one gland it follows that changes in the other glands will occur. In loss of thyroid gland the gonads are also disturbed, in pregnancy the anterior part of the pituitary gland is augmented. One can, however, distinguish between a disease caused by a single gland and a disease of pluriglandular nature caused by simultaneous disorder of several glands.

In the case of Mongolism, described for the first time by Langdon-Down in England in 1867, there is much to be said for the theory of autotoxaemia. The face formation with epicanthic folds, the microcephaly, hyperbrachycephaly, and the arrest of growth indicate a retardation of development. It is scarcely necessary to mention the weak joints and the indented tongue. It is a well known fact that cases are often combined with other degeneration of thyrogonic and hypophyseogenic type. The simple type of convulsion in the brain signifies also a retardation in development. I could show in the formation of the cortical cells embryonic characteristics, but recently a degeneration of the third cortical stratum and also a species of malformation in the cerebellum has been described. I cannot endorse van der Scheer's theory that the cause of Mongolism is a hard constriction by the amnion. The exhaustion theory is deduced principally from the fact that usually the last child of a large family, and especially the children of an elderly mother, become Mongoloid.

But apart from histology the serology can also contribute to elucidation of the matter. In our laboratory Kafka firmly established the fact that the serum in most cases shows a weak but distinct "decomposition" reaction of the hypophysis. The white blood corpuscles are increased, especially the neutrophils and also the eosinophils, the rate of sedimentation is augmented, and the viscosity of plasma is decreased. Distinct syphilis reactions are absent, and a syphilitic origin, so often expressed, cannot be upheld.

The most important of all problems, however, in psychiatry is the pathogenesis of dementia praecox or schizophrenia, and the greatest problem in the treatment would be its cure or amelioration.

Doubtless there is a recessive heredity, certainly in 70 per cent of cases. There is also anatomical alteration in the brain, as manifested by Alzheimer, Rosenthal, Josephy, Klarfeld, and Fünfgeld. A transformation in the nervous cells is found in the third stratum, which is very liable to degenerate. The fifth stratum is also changed. Principally an atrophy of nervous cells can be demonstrated, the chromatin disappears, the cell is cloudy, the basic substance shows a wavy design, the nucleus is changed, and its membrane becomes thinner. The sixth stratum shows some swelling in the nervous cells. Von

Monakow claimed to have found changes in the choroid plexus.

The disease is independent of exterior influences, such as psychical and physical, also of exhaustion and head injury.

Several details indicate a relation to auto-toxaemia through internal glands. It is important that doubtlessly some women become ill first or after a remission during pregnancy or childbirth or in lactation.

The contention of Mott and Prudon Such is not generally admitted, that spermatogenesis ceases and that the Leydig cells degenerate with pigment formation, while the sexual organs in females are small and infantile.

Rudolf Allers emphasizes the initial fall and later increase of the bodily weight. Corpulence in the chronic stage is often a sign of ill omen. Secretion of saliva and perspiration fluctuate. The temperature is sometimes subnormal, especially in stupor.

The establishment of the internal secretory degeneration according to Abderhalden is held in doubt, but in my opinion is extremely important. One must consider the somewhat difficult method of dialysation, the refractometric research according to Pregl, the interferometric research according to Hirschl, and the basal metabolism.

The method of Abderhalden, first recommended by Fauser, and very much employed in our clinic by Kafka, shows in the actual dementia praecox degeneration of the cerebral cortex, of the sexual glands, and often of the thyroid and pituitary. The blood shows normal coagulation. Antitrypsin is somewhat augmented, cholesterol is fairly high (0.3 to 0.5 per cent, as compared with 0.13 to 0.2 per cent in normal cases).

According to W. Schmidt the physiological augmentation of blood pressure through adrenaline is absent in catatonnia and hebephrenia. In many cases no dilatation of the pupil occurs on instillation of adrenaline.

As S. Fischer proved, the specific dynamic albumin effect falls in initial dementia praecox, and later the basal metabolic rate. It is also probable that during convalescence, so long as there are psychical symptoms or disorders of metabolism, especially obesity, first the specific dynamic albumin effect becomes normal and afterwards the basal metabolic rate. In cases of complete recovery both are normal.

The secretion of organic matter in the urine is often diminished. According to Rosenfeld there is a retention of nitrogen to as much as 2 grams a day. Strübing found the secretion of nitrogen less in cases of stupor. Pighini contends that a decomposition of albumin and negative balance of metabolism occurs in the acute stage, but retention of nitrogen in the chronic stage, also he described an increased excretion of sulphur in acute stages, the synthesis of urea is apparently diminished.

According to Strübing the secretion of phosphoric acid is lessened in stupor. Corvict found considerable indican in the urine in cases of stupor.

Some authors describe glycosuria. Riveno found acetone in 3 of 10 paranoids. Albumin in the urine is found principally in stupor. The function of the kidneys appears slower in the secretion of methylene blue.

According to Pighini the metabolism of salts in the urine is lower, while Lowy describes an increase in the colloids.

Recently Kafka succeeded in demonstrating that a pathological albumin can be found in the cerebro-spinal fluid of dementia praecox less than in general paralysis, but distinctly more than in normal cases. It is an increase of the total albumin of the globulin and the albumin. The albumin quotient is similar to the normal.

Many details, however, are not yet sufficiently confirmed. Some of these refer to changes of secondary importance. It is, however, certain that auto-toxaemia and auto-intoxication are very important in schizophrenia, but do not form the only basis.

Doubtless we are ignorant regarding the relation of cerebral co-operation with the total organism, more especially the disorders of isotonnia, isothermia, and isotonnia too little known. We are, therefore, only able to form a very incomplete idea of the nature of schizophrenia.

The first condition is the inherited quality of the brain. We must certainly reckon also with an hereditary quality of the glands of internal secretion.

If a disorder of metabolism, principally of the internal secretions, affects an abnormally inclined brain, the condition which we term schizophrenia is present. This can be relieved or may become chronic, according to the lesion of the brain.

Of quite a different character are the basic conditions of cyclothymia or manic depressive psychoses. This disease occurs in persons liable to attacks of opposing symptoms—now of exaltation, now of depression, then of excitement or of retardation, then in flight of ideas or in mental slowness. It is much rarer than schizophrenia. Perhaps the most interesting cases are those which pass off in a slighter degree, do not require treatment in institutions, and sometimes reveal themselves temperamentally.

The hereditary factor is here very important, and can be traced in 90 per cent of the cases.

There is no question in this condition of an anatomical basis either macroscopical or microscopical, although occasionally small foci are found in the brain.

There are some interesting physical symptoms. In the mania the bodily state appears excellent, the patients look much younger, and show a "turgor vitalis."

Williams declared that the temperature in mania is increased, and in depression decreased. Toulouse and Marchand reported in mania 0.6 degree increase at night and 0.2 degree in the morning. Other authorities deny this, including Piltz. The pulse in mania is more rapid, in depression slower. The sphygmogram shows in mania steep curves in depression a slow ascent and flat curves. The blood pressure in mania is low, 110 to 120 mm Hg, sometimes even less, to 60, in depression it is somewhat higher, 130 up to 170 mm.

The blood contains in mania less haemoglobin and fewer red blood corpuscles. Macphail states that the haemoglobin content runs parallel with the weight of the body. Antitrypsin and cholesterol are normal. Any "decomposition" of internal secretion, according to Abderhalden, is not traceable. The respiration rate is quicker in mania, but slower in depression.

According to Pini the amylolytic effect of the saliva is augmented in mental excitement. In depression the flow of saliva is reduced, sometimes an offensive odour from the mouth is noticeable. In mania the appetite and thirst are active, sometimes even to voracity; in depression there is loss of appetite to refusal of food. In grave depression the free hydrochloric acid in the stomach is reduced. The basal metabolism appears normal (according to Bornstein). The urine may be augmented in mania up to six times, of a low specific gravity (1001). More uric acid and xanthin is secreted, less phosphoric acid. In depression uric acid and phosphates are less. In mania glycosuria has been found sometimes. Acetonuria in depression is caused by disordered digestion.

Metabolic disorders are generally very slight, and can only be explained as secondary symptoms, digestive troubles especially are caused by depression. It is possible in cyclothymia to find some relation to endocrine processes, but much more seldom than in schizophrenia. There are relations to Graves's disease, in myxoedema states of retardation with depression exist. Vagotomy is not distinct.

In rare cases I have met with a combination of cyclothymia and acromegaly. One can observe the pyknic habitus in real manic patients: the broad face, short neck, deeply vaulted chest, fat abdomen, and somewhat short extremities.

Sometimes manic-depressive disorders appear only as a symptom of illness from other cause, in syphilis of nervous system in old age, in brain alteration, but in my opinion we cannot attribute great importance to auto-toxaemia in cyclothymia. Generally speaking, it is an instability of affective mind caused by heredity, and connected with vasomotor fluctuations.

Auto-toxaemia is of the greatest importance in epilepsy, although this is not a disease in a strict sense, but actually a disposition to reactions which show the different limitations of the consciousness, and, as the most conspicuous syndrome, the classical fit. The difference between true and symptomatic epilepsy is absolute. True epilepsy is applicable to those cases which cannot be otherwise

explained. It would be better to term it cryptogenetic epilepsy.

Very different are the forms in symptomatic epilepsy, as, for example, innate brain disorder with microcephaly, quite peculiar is tuberose sclerosis and the heredito-degenerative processes—pseudo-sclerosis, myoclonus, etc. Further lesions are due to trauma, parasites, and abscesses, syphilis is important, as also are tuberculous acid and encephalitis. Important, too, is the group of infantile paralysis. There also occur pre-senile gliosis and multiple sclerosis, and troubles of disarticulation by embolus, thrombosis, end arteritis, and aneurysm, finally, through poisons such as alcohol, absinthe, lead, cocaine, and camphor.

So-called secondary epileptic fits occur in uraemia, eclampsia in childhood, etc. We must not forget that in cases of true epilepsy it is possible to find certain alterations of brain through careful research. Alzheimer found gliosis of the cerebral cortex in some cases, and, according to Chassin, alterations in the cornu ammonis occurred in 60 per cent of cases. Spielmeyer found a condition approaching leptomeningitis and arachnitis, and also alterations in the circulation and pressure of the cerebro-spinal fluid, sometimes also heterotopias and horizontal cells, according to Cajal.

Certainly heredity is an effective factor—often alcoholism in the father—whereby cerebral resistance is weakened. Before the actual fit the blood vessels are contracted, as Olfried Forster maintains, the brain is anaemic and smaller in volume. The cerebro-spinal fluid pressure is low, according to Cobb and Macdonald in experiments on animals.

Then a very strong stasis of the veins follows the fit, the surface of the brain becomes blue-violet, and the volume of the brain and the cerebro-spinal fluid pressure are both increased.

According to de Cimus the quantity of the urine declines before the fit. Retention of nitrogen in the form of circulating albumin follows, and also increase of the acid elements soluble in ether, sometimes also of the uric acid, and increase of the antitryptic qualities. The basal metabolism points to oxidation processes.

After the fit the quantity of urine is increased, as also are the acidity, the uric acid, the ammonia, and the total nitrogen, also creatinine, amino nitrogen, phosphoric acid, and organically fixed phosphorus.

Noticeable, too, is the appearance of lactic acid, acetone, albumin, urine casts, and diazo reaction. In the blood there is an increase in the residual nitrogen and in antitrypsin, and there is a trace of lactic acid. These alterations appear in consequence of a lack of oxygen and superfluity of carbonic acid in consequence of increased muscular effort. The antitryptic qualities of the blood are enhanced. The secretion of gastric hydrochloric acid is diminished. The most important is retention of the nitrogen, which does not build up the body albumin, but represents albumin in circulation.

The epileptic shows a decreased production of carbonic acid between the fits. Before a fit the oxidation is completely retarded, and after a succession of fits the production of carbonic acid is again somewhat increased.

In the importation of albumin the metabolism of gas is reduced in consequence of retarded oxidation before a fit. The production of carbonic acid is reduced, as the combustion is not extended to the final products. The metabolism of fat shows only slight deflection.

The specific dynamic albumin effect is slighter than with healthy persons. According to Allers the most important fact is that the retention of nitrogen is caused by the augmented circulation of albumin. The ability to form carbonic acid is diminished in epilepsy. Before a fit the albumin is incompletely oxidized, afterwards it is replaced in higher degree. Toxic products of metabolism in consequence of incomplete oxidation before the fit are secreted through the kidney. Normally the central nervous system maintains the equilibrium between acids and bases, this regulation is disturbed in epilepsy. The fit seeks to establish a balance. It alters the metabolism, the exchange of albumin is increased, the white blood corpuscles are diminished, and the toxicity of the urine is intensified.

The irritants by which an attack is induced are different in nature. By far the strongest is faradization of cortex

cerebri, further mechanical, chemical, or toxic irritants can net in the same manner

Some factors precipitate convulsions—as, for instance, pressure on the carotids, blows on the skull, lumbar infiltration of air, and sometimes lumbar puncture, also sensory irritants, such as pressure on peripheral scars, operative irritants, worms, and affects, especially shock with angiospastic effects

The liability of the brain to convulsions is augmented by certain secretions. Of these the secretions of the suprarenal gland, of persistent thymus, of the corpus luteum, perhaps even the epiphysis cerebri, increase excitability, on the other hand, the parathyroid glands, the sexual glands, the pituitary, and perhaps the pancreas decrease the tendency to convulsion. The thyroid gland is ambivalent. It is probable that the glands influence the proportion of potassium ions and calcium ions

It is important that in epilepsy we can also show in the blood serum the "decomposition" of internal secreting glands, especially the thyroid gland, also to some extent the sexual gland and also the suprarenal gland. These reactions are generally less intensive than in schizophrenia, but they are often important in the differential diagnosis from hysteria

I would mention that the removal of a suprarenal gland by operation has absolutely no effect on recovery. However, many factors can predispose the brain to convulsions, different irritants, among these also auto-toxaemia, can prepare the latent convulsion until finally the convulsion appears by summation or by the addition of a new irritant

The influence of the liver in mental disorder is still somewhat uncertain. Most probably it is a factor in Wilson's disease—progressive lenticular degeneration. The tissue of these centres in the brain is disintegrated with formation of granular cells, but the process also occurs in the cortex cerebri. According to Alzheimer the giant glial cells may sometimes be found, further, a nodular cirrhosis of the liver is present. According to Hall there is an innate inferiority of the liver and the brain. The differential diagnosis as compared with other diseases of the extra pyramidal system is not exact

Kirschbaum examined the central nervous system in three cases of acute yellow atrophy of the liver, and found degeneration in the corpus striatum and in the pallidum, and also in the cortex cerebri. In experiments on animals in our clinic he also found that with elimination of the liver no serious damage in the corpus striatum and in the pallidum occurred

Formerly great importance was attached to bodily exhaustion as an initial cause of mental disease. A number of disorders were classified as exhaustion psychoses, such as amnesia and mania delirium. Cases of shipwrecked persons, exposed for a long period to hunger, were described as being delirious. But here probably also psychical causes were at work, principally fear and desperation. Sometimes a mental disorder could be observed as early as the second day

In speaking of exhaustion we must distinguish between bodily exhaustion (fatigue) and lack of sleep and lack of nourishment. Bodily strain has a more harmful effect on the heart than on the nervous system. Lack of sleep can, of course, cause disorders in a normal mind. Proportionally small is the influence of hunger. I have made experiments myself and established that three days without nourishment caused only a very slight lapse of memory and of the association of ideas, whereas perception is well preserved. On the other hand the mental qualities declined very quickly during a sleepless night

Also the brain of animals killed by hunger experiments is much less affected than the brain of those dying from lack of sleep. The war furnished a gigantic experiment in respect of exhaustion, also of opportunities of observing the influence of hunger on insane persons, but the result was negative. A paranoid woman, five and a half feet in height, decreased in weight by as much as 24 kg. or 53 lb., without any alteration in the mental condition. Thus exhaustion only has a very slight influence in causation of insanity, and least of all lack of food

Our summary shows that in psychoses an extraordinary

quantity of biological and chemical changes occur which can be explained by auto-toxaemia. In part these are secondary symptoms of illness due to other causes, as in the case of general paralysis

In part, however, these disorders must be attributed to causal factors. The cause of a psychosis is not so simple as a chemical reaction. In general, it is a question of a collection of factors. Primarily an innate disposition, especially both in the central nervous system as well as in the vegetative nervous system and in the system of endocrine glands. This is so in cases of idiosyncrasy and feeble-mindedness with disorder of the glands, as well as largely in dementia praecox, but if these conditions are present they are often succeeded by external and internal irritants as in epilepsy

An important question is: Can the treatment utilize this point of view? In some ways this has already been done. Most successful are cases of myxoedema and cretinism. These diseases will soon disappear altogether but in this the prophylaxis of endemic cretinism will contribute by the purification of water and the application of small quantities of iodine

Results are possible in pituitary disorder by treatment with x rays, and more by radium and by operation, but sometimes also in diminished function of the glandular part by the administration of organic substances, such as fresh animal glands, prepared glands, or glandular extracts. A number of other "organic" treatments are more important in neurological cases than in psychiatry. Also opportunity of treatment is offered in cases of epilepsy

Unfortunately the fever treatment with malaria and relapsing fever, which we also employed in our clinic in cases of dementia praecox, epilepsy, multiple sclerosis, etc. has not as yet had positive successes. Also other treatments of dementia praecox with organic substances and blood transfusion yielded no result

To be sure Wolfgang and von Wieser of Vienna report successes in disorders of the internal secretion by x ray treatment. First, the ferment reactions of Abderhalden and the basal metabolism must be specified, whereupon irradiation of the endocrine glands with x rays follows. Wieser has already treated 98 cases of idiosyncrasy, including Mongolism, and in 94 cases the clinical condition and the quality of serum were improved. Besides these numerous other disorders of psychical, neurological, and endocrine character were treated. The reports thereon are certainly worth following up

Both diagnosis as well as therapeutics demand that the research of the auto-toxaemic influences in psychoses is to be regarded as one of the most important tasks in psychiatry

VISUAL EFFICIENCY AND WORKING ABILITY

BY

A. FREELAND FERGUS, LL.D., M.D.,
F.R.F.P.S. GLAS.

Honorary Surgeon Glasgow Eye Infirmary

It would perhaps have been more in consonance with the subject and with the contents of the following contribution had the title of the discussion been "Visual inefficiency and working ability," for the burden of my story is that much work can be done by persons who suffer from very defective eyesight

Advancing years, if they have not brought wisdom, have perhaps brought a certain amount of caution. At any rate, I had much rather sit and listen to people nowadays than air my own opinions, still, I think I am not wrong in saying that the origin of this discussion was a communication which I read to the Royal Philosophical Society of Glasgow on October 19th, 1927. In that communication I advanced my reasons for holding that for most forms of manual work visual acuteness, in the strict sense of the term, is scarcely required at all. That paper, by the courtesy of the late Sir Dawson Williams, whose death I much deplore, for I knew him intimately for forty years,

* Read in opening a discussion in the Section of Ophthalmology at the annual Meeting of the British Medical Association Cardiff, 1928

was published in the *British Medical Journal* of January 14th, 1928 (p. 42)

Our textbooks have a good deal to say about foveal, or perhaps I should say macular, vision, that form of vision which I shall hereafter call visual acuteness, and by which ordinary types used in printing are recognized, and reading and writing made possible. This function of visual acuteness is specially prominent in one part of the field of vision, and I incline to restrict the term visual acuteness—Dor's diagram notwithstanding—to macular vision. The field of visual acuteness has not yet been accurately measured. I have made some attempts to measure it by two different methods, but there are many sources of fallacy, and results can only be taken as approximately correct. It may, with tolerable certainty, be said that the field of visual acuteness, or if you like the phrase better, macular vision, does not exceed two degrees in the total field of vision. So far as my observations go it is not circular or oval, but rather larger from side to side, than from above downwards. A recent experiment may here be noted. I found that at a distance of 120 inches from a set of Snellen's ordinary test types I could not distinguish even the large π at the top of the scale at a greater angular aperture than eight or ten degrees. By that I mean that the line between the π and the nodal point of my eye made with the line between the point of fixation and the nodal point an angle of eight or ten degrees. With a greater angular aperture I could see the black and white, but could not have told that it was the letter π . People, if they like, are entitled to call that visual acuteness, but it is widely different from the special function of macular vision. With enormously greater angular aperture I could still see objects in the room quite distinctly, and could have avoided them had I been in motion. The binocular field of vision in the horizontal meridian extends to about 184 degrees, to use nautical language, it extends from about 2 degrees abaft the starboard beam right round to about 2 degrees abaft the port beam, and in the whole of that excursion the macular vision, if any point in the arc be made a point of fixation, is not greater than two degrees in eumetropia.

In myopia, say of four dioptres, the far point of macular vision is approximately at ten inches, or twenty-five centimetres. Beyond that there is practically no field of visual acuteness for such an eye, in the strict sense of the term. Now I have again and again recorded cases of persons with very high myopia who suffered no inconvenience therefore in their work. Thus I have on several occasions given accurate details of colliers with high amounts of myopia, who had no difficulty in making as much money as the best sighted collier could, and what is true of coal-mining is true of almost every other form of manual work. To return once more, and briefly, to the field of vision, outside of the macular field objects can be seen almost to the extreme of the peripheral field. The details, no doubt, cannot be made out, but if the eye be healthy, objects are not only distinguished, but it is possible to estimate their positions relatively to each other. One essential in the peripheral location of objects is the sense of projection, and another very important feature is the subconscious estimation of distance. The first no doubt depends upon such factors as the light sense and the colour sense. Objects in nature stimulate the parts of the retina on which their images are formed differently, according to their luminosity and their inherent colour, or lack of colour, and their shape. I have always felt that the light sense is not nearly so much studied as it should be, and in modern times that neglect is all the more unjustifiable, for we have now many good photometers which are of easy application. In macular vision the intuitive estimation of distance, or what I may, without raising an argument, call the subconscious estimation of distance, is a very important factor, to a considerable extent it supplies the place of stereoscopic vision. One of the best artists that we had in Glasgow during the last half century was a gentleman who all his life enjoyed the use of only one eye, the other from his early childhood being quite blind, and yet so far as perspective was concerned his pictures did not show any defects. He was a draughtsman of the first order, and his drawing was always correct. The

factors that determine the subconscious estimation of distance are very numerous. Here I can only mention a few. In binocular vision the most important is the function of convergence—the nearer the object is the greater the amount of convergence required. That important factor, however, is not available to persons who have only one eye, like my artist friend. There are at least three factors which in these circumstances come to be of service—namely, the size of the retinal image, the amount of accommodation used for fixation, and the parallax. A very important factor is the subconscious mental checking of the physical data. Where a person is seen at a great distance along a high way the retinal image is much smaller than if the same man were seen near at hand. The observer knows quite well that the height is the same and that the man, as he approaches, has not for some obscure reason become larger. On somewhat similar lines the distance of objects is to a considerable extent determined by the comparison of the object under observation with other objects in the same neighbourhood whose sizes are approximately known to the observer, that is a matter of education, or at any rate of experience in life.

Another very important feature in the estimation of distances, and in determining the relative position of objects, is parallax. If there are two objects and one is seen to move in front of the other, then it is obvious that the object which so moves is nearer than the other. Similarly, when an observer changes his position he may see an apparent movement in the objects surrounding him.

When binocular vision is absent, and when there is no impulse of convergence, then to a very considerable extent its place is supplied by the following factors: differences in light and shade and probably in colour tone; apparent size of objects and the intuitive comparison with objects the sizes of which are approximately known.

To my way of thinking—I speak with deference to the presence of so many colleagues whom I regard as more authoritative than myself—the macula has both visual acuteness in the restricted sense in which I use that term, and field vision. The special function of macular vision seems never to be called in except as a volitional act. As a man walks along a street the images of various objects, such as signboards and posters and other things, are formed on the macula, yet he never appears to see them except volitionally. A person may stand before a large bookcase filled with books, the images of some of the titles must be formed on his macula, and yet that fact does not give rise to consciousness, it is only when he begins by a volitional act to examine the labels that he becomes acquainted with the contents of the case.

The sense of projection, or, in other words, the power of locating various objects in their proper positions, is alike common to binocular and to monocular vision. To illustrate that point, I put two coins on a table, one immediately in front of me and the other considerably to the side, and with both eyes open I look steadily at the one immediately before me while doing so I have no difficulty whatever in striking the other one with my hand, or, if the distance be too great for my arm to reach, with a stick held in the hand. If the experiment be repeated with one eye shut it is not found more difficult to strike the coin which is peripherally situated.

Now to give a few practical examples in confirmation of the preceding remarks. The first condition to which I shall call attention is the one already mentioned—namely, myopia. A man with ten dioptres of myopia does not require to bring his eyes to four inches from a tramcar before he sees it, nor does he require to put his eyes to four inches from the step of the vehicle before he mounts into it. His peripheral vision enables him to distinguish the car and to get into it, if he so desire, like any ordinary mortal. His peripheral vision enables him to walk along a street without jostling his fellow men. He can tell the colour of a car at a considerable distance, and for the most part can also tell the colour of a light. It is only when he comes to read such things as the names of streets or the direction boards on cars that he fails. I have elsewhere mentioned the case of a man who is blind of one eye and who has several dioptres of myopia in the remaining eye, and who yet has driven his own motor car

for many years without coming into collision with any object so also a person with a moderate amount of myopia can make out land or other ships nearly as well as an emmetrope. In the communication which I made to the Royal Philosophical Society in Glasgow I narrated that when I made my eyes artificially myopic by putting a spherical +3 in front of my correction I could, on a night when there was no moon but starlight, quite well make out islands eight miles away from the place where I was standing. On the other hand, in daylight, in the same circumstances, that is, with an artificial myopia of approximately three dioptres, I could not see a rowing-boat at a distance of a mile. There is, however, an important factor to be taken into consideration and it is that the interpretation of retinal images probably differs very much in those who have made themselves artificially myopic from what it does in the case of persons who, having been myopic from their earliest days, have been interpreting defective images formed on the retina all their lives. Interpretation is not a physical process, it is mental. It is the mental process by which the individual interprets the effects of physical stimuli. No mechanistic theory is at all adequate to explain the facts of vision sufficiently. The mind determines the function rather than the function the mind.

Here I may mention another very important group of cases well typified by one of my friends who is very amblyopic in one eye, for in early life he suffered from concomitant convergent squint. He is a medical practitioner and is a great deal in his motor car. He drives about his district without any trouble, notwithstanding his amblyopia and the high degree of refraction error which he has in each eye. No railway company would for a moment employ this man yet he has no difficulty in driving his motor car and none so far as sight is concerned, in his work as a general practitioner. One question has often occurred to me in connexion with squint amblyopia—namely, is the periphery of the squinting eye available for stereoscopic vision? If the angle of squint is a constant and the image of a distant object is focused on the macula of the non squinting eye, then the image of the object will always be focused on the same point of the squinting eye and so for every other point of space. Does this, then, supply the convergence factor in the subconscious estimation of distance? I hardly think that it does, for about 1906 I called attention to the value of plastograms in the detection of amblyopia of one eye. When the coloured objects are viewed through the coloured glasses and the observer's head is moved slowly from side to side, the objects in view are seen also to move if neither eye suffers from amblyopia, but there is no movement if one is amblyopic. Now I have found that a squinter with any considerable amount of amblyopia never sees any movement. In such cases the convergence element apparently must be eliminated, and yet there are many persons with only one good eye engaged in all the ordinary occupations of life, much to the benefit of themselves and of the country. For some years back I have been noting cases of defective sight and the work which some defective sighted men can accomplish.

Another matter has claimed my attention—namely, the fact that many men who have sufficient sight for their work are thrown out of employment because someone has discovered a trivial defect which has not interfered with the person's working power, but which has caused the insurance companies to refuse to accept any risk no matter how slight. Many persons are said to be on the dole because of laziness, and that seems to be perfectly true but a number of people, by no means loafers, are on the dole because they have some trifling defect, very often of little moment, which the insurance companies regard as a risk that they will not accept. To a considerable extent the dole is the necessary corollary of the Workmen's Compensation Act. A man may be quite able to work, and may be more than willing to work, and yet for some trivial condition be prevented from doing so by this Act. The time is not far distant when, before an employer allows a man to enter his service, he will require to be thoroughly examined and if any defect is found he will be rejected. It is difficult, but probably not impossible, to devise some scheme

by which a man, if found defective, might be employed without the employer running any risk, at any rate on account of accident due to that defect. The more obstacles that are placed between an employer and a workman, the greater will be the number of men kept out of work, eked out in dire poverty what might have been a useful and comfortable life.

Under the auspices of the Corporation of Glasgow, some years ago I inspected a large number of blind persons as to the causation of their blindness and in addition to that I took careful note of the occupations of each person seen. A good number of them, although defective in sight, were able for a fair amount of work. I came across two cases of persons who were almost blind, and still able to get about the streets of Glasgow and do their work as street lamp lighters. Nobody at present would think of starting a man with defective sight in any such employment. One of the two told me that he was giving up his work because the motor traffic in Glasgow made the streets very dangerous for him. He had less difficulty at night than in broad daylight, because he could distinguish lights much more easily than he could distinguish objects.

Perhaps I cannot conclude this somewhat discursive paper better than by giving a few more instances of persons afflicted with defective sight and still doing a great amount of work.

J A., aged 27 seen at the Blind Clinic. This patient has full, 20 dioptres of myopia yet he has enlisted for the war and actually served abroad. He was after his discharge from the army engaged as a coal trimmer in a steamer and worked as such for some years. Now with 20 dioptres of myopia the far point is about two inches from his eyes notwithstanding that fact he found no difficulty in shovelling coal.

J B. Lost the left eye during the war when seen his right eye was found to be highly myopic and yet for years he was engaged as a railway hauler in a shipyard.

P D. aged 51. In this case the left eye was enucleated when the patient was a few months old. In the right eye the vision is 1/36 this is one of the cases to which I already referred. He has been working as a street lamp lighter for a considerable number of years and is still constantly engaged in that occupation.

J C. aged 36. When she was a young girl I operated on both eyes of this patient for congenital cataract. She has first rate field vision but although each pupil is thoroughly clear and good and the fundus of each eye is healthy, she does not possess that function to which I gave the name of visual netlessness.

J P. aged 25. Employed by Glasgow and West of Scotland Mission to Outdoor Blind. The left eye has been enucleated. In the right eye he has a certain degree of microphthalmia with nystagmus almost certainly congenital. At the time of the examination he was wearing sph. -13 D. but with that lens he did not admit 5/60. Without any glass he is able to read J 6 at about one inch from his eye. On dilating the pupil of the remaining eye the lens is found to be slightly dislocated yet he says that he is able to walk about quite freely and is even able to cycle. He does not in moving about require the assistance of a guide.

H O R. aged 43. Has worked as a miner since he was 12 years of age and has had no difficulty in making good pay. There are about 15 dioptres of myopia in each eye complicated with three dioptres of astigmatism. Each eye showed pathological changes yet this man was able to work quite successfully till he was attacked by miners' nystagmus.

E S. aged 60. Left eye is as a result of injury received twenty years ago completely blind. Notwithstanding his monocular condition he has worked with a circular saw for twenty years.

W S. age not noted. Left eye is divergent and is nearly blind. This condition has been present for many years but he was able to earn his living by pumping air into a diving bell for several years. In coming from Greenock to Glasgow he did not require the services of a guide. He was put out of work because his employers or their insurance company were afraid of accident on account of defective vision.

G F. Age not noted, but an elderly man. Incipient cataract in each eye vision 3/9 in each. This man is able to continue his work as a blacksmith.

G W. aged 18. Has 50 dioptres of hypermetropia in each eye. He was not allowed to wear his correction in the shipyard in which he was employed and was dismissed on account of defective eyesight and now in spite of efforts made to get into some form of work he is on the unemployed list.

The cases which I have mentioned could be added to indefinitely from the large amount of clinical material which I have collected in past years. One conclusion seems to me legitimate—namely, that while Snellius's letters enable us to form an estimate he it said only a very rough estimate of what a man may do with visual acuteness, there is no method of estimating, even in the roughest manner, the value of field vision. Macular vision seems to me to differ so widely from field vision that I cannot regard

them as forming a continuous function. Correction of errors of refraction is essential for macular vision, within wide limits such correction is not necessary for field vision.

The questions which have been raised seem to me to be of great importance, not merely from the ophthalmic, but also from the economic point of view. The whole subject requires a much more extensive investigation than it has yet received, and I am specially glad that the gentlemen who are to follow me are very authoritative in such matters.

It may interest the meeting to know that in the eighties of last century I wrote a note to the vice-chairman of the Glasgow School Board to urge that the eyes of all the children under the care of the board should be carefully tested. He replied that neither he nor his colleagues saw any necessity for any such step being taken. Now for centuries before eye-testing became an accurate process many people did a great deal of fine work, and no doubt in these days there was the usual proportion of emmetropic, hypermetropic, myopic, and astigmatic people.

Refractive errors must be carefully corrected for work requiring visual acuteness, but to a great extent such correction is not necessary for field vision. I had no correction till I was five-and-twenty and had possessed myself of a medical degree. I well remember the intense misery of all efforts of reading and writing, for such efforts always brought on frontal headache, and that severely. Field vision, however, caused me no trouble, even although my errors were considerable—namely, in each eye a hypermetropic astigmatism of 1.5 dioptres against the rule and a hypermetropic spherical element as well.

We owe the tests for visual acuteness now in use to Professor Snellen of Utrecht. His tests are all but universally used in all countries, and thus a standard has been fixed which is both convenient and reliable, although, of course, not absolute. Snellen's types, as we all know, consist of ordinary alphabetical letters varying in size with the distance at which they should be read by the normal healthy eye, each letter subtending for the distance at which it should be read an angle of five minutes.

A considerable number of years ago Landolt substituted his broken ring test for letters. It is perhaps a more severe test than that devised by Snellen, and is one on which those who use it place great reliance. The circles in Landolt's rings are also based on the five-minute calculation, but unfortunately, as originally published by Landolt, there is only one ring for each size. That this is not altogether suitable is obvious. It may happen that the opening in the ring corresponds with a meridian that is approximately emmetropic and thus indicate a better visual acuteness than the eye really has. It is quite possible to have the break in the ring clearly seen although there is a good deal of astigmatism. Within recent years a set of types consisting of broken rings has been prepared for the Egyptian Government. For the most part there are several circles for each size, but the break in the ring as printed is either straight up or straight down, or directly to the right or directly to the left. In the official set of types which I possess the circles show defects if these defects involve the vertical or horizontal meridians of the cornea, but may not do so if the meridians of greatest and of least refraction are oblique and not vertical and horizontal. For these reasons I have prepared a series of rings, one of each size, but each ring is capable of being turned by a screw at the back of the apparatus round its own centre.

In testing, supposing the patient at six metres sees the break in the ring corresponding to 6/18, he is asked to look at it as it is turned and to say if the break disappears or if it is quite distinct all the way round. If its distinctness remains then the patient should be put through the same test with the ring corresponding to 6/12. If the break is not seen at all with the circle corresponding to 6/18 then the circle corresponding to 6/24 should be used, and so on.

The head of the patient who is being examined should be held in the same position all through, for an oblique position of the head may easily give an oblique refraction, and that to the extent of masking an astigmatism.

As a means of detecting the presence or absence of an astigmatism, the rotating discs seem to me to be of considerable service, and they are also a help in detecting roughly the meridians of maximum and minimum refraction. They may even be of some use, if carefully handled in the measurement of astigmatism, but for that purpose they are not equal to the fan which we also owe to Snellen, and which is, so far as I can form an opinion, simply invaluable in the correction of an astigmatism.

A British Medical Association Lecture

ON

THE MEDICAL TREATMENT OF GASTRIC AND DUODENAL ULCERATION

DELIVERED TO THE SOUTH-EASTERN OF IRELAND BRANCH OF THE ASSOCIATION AT KILKENNY*

BY

ROBERT J. ROWLETT, M.D., F.R.C.P.I.,

KING'S PROFESSOR OF MATERIA MEDICA AND PHARMACY IN THE SCHOOL OF PHYSIC IN IRELAND. PHYSICIAN TO MERCER'S HOSPITAL DUBLIN.

BEFORE considering the medical treatment of gastric and duodenal ulceration as it is practised to-day it may be well to refer, first, to some of the essentials of the physiology of the stomach, and, secondly, to the little that is known of the causation of ulcer.

The mucous membrane of the stomach secretes a juice which contains two substances of importance—pepsin and hydrochloric acid. Pepsin is an enzyme which, acting only in an acid medium, digests proteins. In this respect it is important, but its action is not essential to adequate digestion of food, as digestion of proteins is effected in the intestine by the action of trypsin. The main action of hydrochloric acid is bactericidal, but it also activates the pepsin, and is necessary for the production of secretin. It is present ordinarily in strength of from 0.1 to 0.2 per cent. of the secretion, rarely exceeding the latter figure. In normal circumstances gastric juice is secreted when the appetite for food is roused, during the act of eating, and for a little time afterwards. During fasting, however, secretion is almost at a standstill, and the juice becomes nearly neutral in reaction. During digestion, according to MacLean, as the production of hydrochloric acid diminishes there is more and more secretion of neutral chlorides. It cannot be too strongly impressed on the mind that in no concentration of hydrochloric acid which has ever been observed in the stomach has it any digestive action. This is not to say that it may not have an irritative action on an unprotected surface. In health a small meal is completely out of the stomach in two hours, a large one in five or six.

CAUSATION OF ULCERS

When we come to consider what is known or thought of the origin of ulcer we find little certainty. It is not my intention to recount the various theories that have been put forward from time to time, but there is no doubt that if a portion of the mucous membrane of the stomach or of the duodenum close to the stomach, loses its self-protective power against the gastric juice it will be digested. All of us who have made *post mortem* examinations some hours after death are familiar with the considerable degree of digestion which has taken place. Not only is the mucous membrane digested, but not infrequently the muscle is also attacked, so that the contents of the stomach may be set free into the abdomen. In this case, soon after death the epithelium has lost its self-protective power, while the juice lying in the stomach has still peptic action, adequate to produce digestion of some of the tissues of the stomach. If we assume that, from some unknown cause during life—and the cause is unknown—a limited area of epithelium loses its protective power against pepsin, then ulceration of that area is likely to occur. It is noteworthy

* A few introductory paragraphs sketching the development of the treatment of gastric and duodenal ulceration during the past forty years have been omitted.

that the appearance of a gastric or duodenal ulcer is quite unlike that of an ulcer of the ileum or colon. In the latter situation severe inflammation and necrosis precede ulceration, in the former there is no evidence to suggest that there is any inflammation precedent to ulceration, and one never finds any necrotic material. It is noticeable that ulceration of this digestive type—now generally known as peptic—is never found in an area bathed in alkaline fluid. It only occurs in the stomach, in the duodenum (usually close to the pylorus), and occasionally in the jejunum when a gastro-enterostomy has been done and a part of the mucous membrane of the jejunum is exposed to the acid gastric juice. It is a striking fact that trypsin, an enzyme of much greater proteolytic power than pepsin, does not appear to have any capacity to produce ulceration in the intestine. Acidity is found, therefore, to be essential to the occurrence of peptic ulceration, although hydrochloric acid of itself, in any concentration that may be present, has certainly no digestive power.

There are few words in medicine which have been so over-worked as the term "hyperchlorhydria", and few hypothetical conditions which have been credited with so much active mischief. We know nothing of the relation of acid to the formation of ulcers. We can hardly say that we know anything of its power of preventing the healing of ulcers. But as a practical fact of observation we know that a persistent acidity of the gastric juice is a frequent accompaniment of ulceration, and that it is a frequent source of pain when ulcers are present. We want to note that it is the persistence of acidity of the juice, rather than excess of acidity, which is the important abnormality.

MODERN TREATMENT

Professor Faber of Copenhagen, in a recent paper, has put forward the view that acid dyspepsia, gastritis, and gastric ulcer are three closely allied conditions, if not indeed, different phases of the same condition. Whether this be true or not, the practical fact emerges in treatment that if we succeed in keeping the acidity of the gastric juice at a persistently low level or are able to keep the juice alkaline, gastric ulcer does not occur, and if it has already occurred healing takes place. The clearest proof of this has recently been given by Professor MacLean and his colleagues at University College, London. They have shown, with the help of x-rays, that complete healing of ulcers some of them of many years' standing, can be brought about by what they call the intensive alkaline treatment. This recovery takes place not only in acute cases but also in chronic.

Let us now face the actual problem of treating a case of gastric and duodenal ulcer on medical lines. It goes without saying that the details of the treatment will depend largely on the special features of the individual case. If there has been severe hæmorrhage one proceeds with great caution and very slowly. Of the treatment of hæmorrhage itself I will only say that morphine hypodermically and the administration of normal serum appear to furnish us with our best defence. After hæmorrhage one would hesitate for a couple of days to give anything but ice or cold water by the mouth. Thirst may be relieved by saline enemata, and, if necessary—though this is rarely requisite—nutritive enemata may be given. The old custom of treating severe cases by rectal feeding for a week or more has properly been abandoned. And, indeed, most of the substances formerly given in this way were not absorbed at all. It may be said in brief that salt, sugar, and alcohol are the only substances absorbable by the rectum which tend to maintain strength.

DIET IN THE ACUTE STAGE

Except in cases of hæmorrhage feeding by the mouth may begin from the first. Our guiding principle in regard to everything to be given by the mouth is simple—give food which does not stimulate the secretion of gastric juice or the movements of the stomach. The old methods of feeding still hold the field—we rely on milk and eggs. At first I am in the habit of giving milk or milk and cream and albumin water in alternate feeds at two hourly intervals. The quantity of either given at a time varies from two to four or five ounces, according to what the patient can comfortably take, and to the stage of the

disease. With fluid food of this simple kind, associated with the drug treatment presently to be described, and, of course, rest in bed, pain usually disappears in a few days.

As soon as the pain has disappeared, beaten-up eggs can be added to the diet—at first one, and soon two or three in the day. Food should still be given in small bulk and at intervals of not more than three hours (Lenhartz's treatment in its full rigour means over-feeding, as regards patients in this country at least, who are easily nauseated by a large number of eggs or by raw food). In the second week bread and butter and biscuits, such as crackers (which cannot be swallowed unless well chewed) may be added gradually. Also soft milk foods, such as blancmange and well boiled tapioca, and later, rice may be added. Acids, jellies, soups, and meat extracts are better avoided, as they tend to excite gastric secretion. In the third week light steamed fish and boiled chicken come into the diet. In the fourth week mutton and light meats generally can be taken, and thereafter the diet becomes very liberal.

GENERAL TREATMENT

In cases that have been severe the patient is kept in bed until the end of the fourth week, and return to normal activity is gradual. In duodenal ulcer one can usually proceed more rapidly as regards food than in gastric ulcer. During the whole course of treatment close attention to the condition of the bowels is required. Phenolphthalein is convenient and pleasant in the early stages and, in the later, olive oil, liquid paraffin, and agar jelly—that is to say, the lubricant aperients are better than the irritating. The mouth wants careful attention. In all cases where a patient is receiving only liquid or soft food careful toilet of the mouth by the nurse is required. A mild stimulant antiseptic mouth wash should be ordered and the nurse should cleanse the whole of the mouth with this several times a day. Over and above this, however, the condition of the teeth—or rather of the gums—is all-important. Caries has little effect on these conditions except in so far as it interferes with adequate mastication but pyorrhoea in any of its stages—and only its more severe stages show pus—probably has a direct action on the production and maintenance of ulceration. Whether this is produced by a direct carriage of septic material to the stomach in swallowing, or in some other way, we cannot say. Dental help must be obtained to have the teeth thoroughly cleaned, and further improvement will be obtained by regular massage of the gums and by the use of an autogenous streptococcal vaccine. When the patient is strong enough to stand the operation it may be necessary to have some of the more seriously affected teeth extracted.

DRUG TREATMENT

It remains to speak of the drugs that will help in treatment, and in regard to this the same principles apply both in the active stage and subsequently. For generations we have relied on what were vaguely called gastric sedatives—bismuth, soda hydrocyanic acid, and morphine in the early stages to relieve pain. These have been given on empirical grounds and there is every reason to believe that they were useful. It is, however, necessary for us to inquire in what way they are effective. Two conditions above all others tend to prevent healing of ulcers—active movements of the stomach and the presence of acid gastric juice. Whether the acidity itself is merely irritating, and likely therefore to cause active movement, or whether it is that the pepsin is kept active by a constant acidity we do not know, but we do know as a clinical fact that every measure which diminishes movements and acidity helps towards the healing of ulceration.

It will be seen that the whole of the treatment which I have been so far describing is based on these general principles. We have kept the patient in bed and we have been careful so far as we were able to give only such food as would excite neither movement nor secretion. In the matter of drugs we must proceed more actively. It is true that it is not always necessary to give anything intended to allay the movements of the stomach, for we refrain from giving anything exciting, and if we give food only in small quantities, then the gastric movements will be reduced to a minimum. As regards secretion the

matter is different. Remembering that pepsin can only act in an acid medium, and that hydrochloric acid may itself be directly irritating to an ulcer, we must endeavour to inhibit the activities of both these substances at one stroke—by rendering and maintaining the gastric juice alkaline.

Bread soda has been for generations a traditional remedy for all kinds of dyspepsia, including, no doubt, many cases of unrecognized ulceration. Sippy gave it a more definite position in the treatment of ulcerative conditions. But the mistake up till recently has been in giving alkali in such small doses as to be comparatively inefficient. MacLean states that small doses of alkali may only increase the acidity of the stomach by exerting an acid secretion. He holds that the alkali must be given in such quantities as to maintain a perpetually alkaline reaction in the gastric contents. In this attempt we have a choice of various substances. I have already mentioned bread soda. It has the advantage of being easily soluble and diffusible, but the corresponding disadvantage of being readily absorbable and therefore temporary in its action. More stable, and therefore more persistent in its action, is bismuth carbonate, which, however, has the drawback of being rather constipating. Intermediate between the two, and definitely laxative in action, is heavy magnesium carbonate. Sodium citrate is another convenient and pleasant form of administering alkali. There is no need to enumerate other alkalis. By a combination of two or three of these salts, varied according to the needs of the case, we can generally keep the gastric juice under control. I have been in the habit for some time of giving doses of 20 grains of sodium bicarbonate with 10 grains of heavy magnesium carbonate, and I have rarely found it too laxative. It is a definite advantage that it is laxative, as thereby the necessity of giving other aperients is avoided. MacLean recommends a combination of one part of sodium bicarbonate and two parts each of magnesium carbonate and bismuth oxy carbonate. In any case one may vary the combination of the drugs used according to the results they produce—(1) in the relief of symptoms, and (2) in their effect on the bowels.

Apart from the alkalis there are one or two other drugs which have a definite effect of diminishing the secretion of the stomach and its movements, belladonna being the most important. We can often do without it, but I have met cases in which alkalis did not give the desired relief from symptoms, and in which belladonna has been rapidly effective. It is only rarely that doses greater than 5 minims of the tincture three or four times a day have to be given, but 10 minims may be given for a brief period if thought necessary. A patient taking belladonna, however, should be kept under frequent observation, and should be warned of the first symptoms of poisoning, and ordered to stop it if they appear.

Oils and fat have a definite inhibitory effect on gastric secretion, but this effect is almost negligible unless they are taken on an empty stomach. A tablespoonful of olive oil, with or without 20 grains of heavy magnesium mixed up in it, taken midway between meals, will keep many people comfortable. In cases where olive oil cannot be taken, cream may be given, as it is almost as useful. The time at which medicine is administered is important, it is governed by the time of occurrence of pain and discomfort in relation to food. Some patients with gastric ulcer suffer from pain which comes on twenty minutes or half an hour after taking food, in such cases the medicine should be given within a few minutes of taking food. In other cases of gastric ulcer, and in nearly all cases of duodenal ulcer, the pain comes on later, often only when the stomach should be empty and when hunger should be reappearing. In these the medicine should be administered one to two hours after food—that is to say, a quarter of an hour or so before the period at which discomfort usually appears. Many people suffer from discomfort at night, and special precautions must be taken to prevent this. A fairly big dose of alkali should be taken as the last thing when going to bed. One or two more powders, with a convenient supply of water, should be within reach of the patient. If he awakens at all in the middle of the night then he should take one of the powders. On waking in the morning it is often necessary to take another.

WHAT TO AVOID

The negative treatment is as important as the positive. The patient must avoid all substances, whether as food or otherwise, which excite gastric secretion or gastric movement. We are now discussing not only his conduct during convalescence, but his rule of life for some time after the ulcer has been cured. While there is any discomfort at all alcohol must be strictly forbidden. Subsequently, only the lightest wines are to be taken, and in strict moderation. I have known several relapses following on the ingestion of little more than a liqueur glass of whisky taken neat. Spirits of all sorts must be abandoned. Wines with low acidity are less exciting than the more acid wines. Some people can take beer or stout without discomfort, but others cannot, and in any case the quantity taken should be of the smallest. Just as injurious as alcohol is tobacco. It has been for many years a clinical observation that tobacco smoking causes acid dyspepsia, and some writers hold that it is an important factor in the production of duodenal ulcer. Nicotine, although it ordinarily diminishes the appetite, increases not only salivary, but gastric secretion. No doubt this is followed by subsequent inhibition. As Dixon puts it, there is salivation during smoking and a dry mouth the following day, what holds of the saliva holds also of the gastric juice. But nicotine has a further action in that it increases the muscular movements of the stomach and bowel after a brief inhibition. People vary greatly in their reaction to tobacco. Some acquire a strong immunity to it, and show no digestive disturbances as the result of its use. Others are more sensitive and easily suffer from acidity, and from a return of the symptoms associated with ulceration. In such cases we must study the reaction of the patient to tobacco, but in all cases we must warn against immoderate smoking. Since nicotine is the only active principle of any importance in tobacco, it is curious that cigarette smoking appears to be more injurious to the stomach than pipe or cigar smoking. This is often explained as being due to the fact that inhalation is more frequently practised by cigarette smokers. But I have frequently seen severe discomfort induced by cigarettes in those who do not inhale. It is quite likely that the heavy cigarette smoker really absorbs more nicotine in a day than the pipe smoker, and, moreover, he is likely to smoke at more irregular and unsuitable times. Smoking does less harm if done immediately after a meal, and it should be altogether avoided when the stomach is empty.

DIET AFTER THE ACTIVE STAGE

Finally, we have to consider the diet to be observed for at least a year after symptoms have disappeared. In the first place we must continue our practice of giving food at frequent intervals, and the patient should never be allowed to remain with an empty stomach or to feel hungry. If it is difficult to arrange meals frequently enough he may carry a few biscuits in his pocket and break his fast therewith. As regards food, it is easier to enumerate the prohibitions than the permissions, for the diet allowed may be thoroughly liberal. The following classes of food should be definitely excluded:

- 1 All highly spiced foods, also condiments such as mustard and pepper in any quantity.
- 2 Acid foods, such as pickles or other food in vinegar, and acid fruits.
- 3 All foods which are likely to leave a solid residue persisting in the stomach. The worst of this class are raisins and currants, the skins of which lie long in the stomach, also such vegetables as lettuce, and green vegetables generally.
- 4 Very hard foods such as nuts.
- 5 Meat extracts and soups, which stimulate the secretion of gastric juice.
- 6 Very sweet food.

On the other hand, meat, both fat and lean, may be given in moderate quantity, cream and butter freely, bread and butter, toast, and biscuits in ordinary quantities. In most cases brown bread, rough biscuits, and porridge can be taken without harm, but the effects must be watched in each case. After gastric ulcer more caution is needed than after duodenal ulcer, and it may be necessary to give

softer food for some time. In every case individual care must be given and each food treated as an experiment. It is clear that the intelligent co-operation of the patient is of the utmost help, and he should be taught to observe with care the foods which cause him any inconvenience. At the end of two years from the cessation of symptoms treatment by medicines may cease and a greater freedom in diet be permitted.

Treatment along these lines gives satisfactory results in the great majority of cases. It is sometimes objected that the time of treatment is long. This is true, but, except for a period of from one to three months at the beginning, the patient is going about freely and is enjoying a liberal diet.

SURGERY

It may be asked whether surgery is no longer to play any part in the treatment of peptic ulceration. I do not think that we have yet arrived at so desirable a position. Apart from such acute emergencies as perforation, in which almost the whole chance of survival depends on speedy operation, such conditions as pyloric stenosis are only amenable to surgical aid (one must be careful, however, to be sure that there is pyloric stenosis, for many cases that appear to be such clear up admirably under medical treatment). Again, where there are adhesions causing pain and discomfort it may be necessary to operate, but, for uncomplicated ulcer, is operation necessary? I think the indications for operation will in future be social rather than clinico-pathological. An uneducated or unintelligent patient will neglect to follow the careful regime that is necessary for the success of medical treatment. A patient in poor circumstances will find himself unable to provide himself with what is required. In these cases I think surgery offers a better prospect. It is necessary, however, to say that if surgery is to get its best results operation must be followed by care nearly as meticulous as that required for purely medical treatment. It is not my object to put medicine and surgery in competition but rather to try to place before you a statement of what a patient may nowadays expect from medical treatment.

A STATISTICAL REVIEW OF GASTRIC AND DUODENAL ULCER

BY

DAVID SMITH, M.D., F.R.F.P.S. GLAS.,
HONORARY ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW

The purpose of this paper is to give the results of a statistical inquiry into cases of gastric and duodenal ulcers treated in Professor Walter K. Hunter's wards in the Royal Infirmary, Glasgow. The records of patients admitted to hospital in the decade 1913-22 have been examined and their after-histories followed up. This was done in 1927, so that the follow-up comprises histories of five to fifteen years' duration. The total number of cases considered is 214—96 male and 118 female. In a survey of this kind the difficulty which arises is one of diagnosis: the undoubted correctness of which is almost impossible to establish. The surgeon and pathologist alone can give us absolute confirmation. The physician deals with the clinical aspect, supplemented by x-ray examination and chemical analysis of the stomach contents after a test meal.

The cases taken in this review are those which have been considered clinically, radiologically, and chemically to be cases of chronic ulceration. The period of survey did not allow of fractional analysis being considered, as the older "wald test meal" method was then in use.

I have, on the whole, not attempted to differentiate duodenal and gastric ulcers, for I am of opinion that while this is possible in extreme cases, it is almost if not absolutely impossible in others. This view of the difficulty of differentiation is upheld when one studies the widely divergent statistics of the incidence of duodenal and gastric

ulcers as compiled by different clinicians and pathologists. Even the surgeon at times finds difficulty in deciding whether an ulcer is duodenal or gastric. His landmark is the pyloric vein, and, like all veins, this is not infrequently aberrant.

HOSPITAL INCIDENCE

The term "hospital incidence" has been used because in arriving at a percentage we have to bear in mind that we are dealing with patients from a very selected portion of the population, who are more or less considered to be seriously ill and are admitted to hospital wards. The incidence from such a source is necessarily high. In the following table of in-patients and out-patients this is made clear, although we must still remember that the incidence, as shown both by in-patients and out-patients, is that of a selected proportion of the population—namely, the working and poorer classes.

Table I gives the incidence with regard to patients admitted to the wards and that of patients attending my own out-patient department at the Royal Infirmary, Glasgow, during a period of five years—1919-24. The out-patients are included for comparison only, and none of these cases comes within the scope of this review. In all percentages estimated in this paper the figure is taken to the nearest whole number in order to simplify comparison.

TABLE I

Sex.	Total Patients	Gastro-duodenal Illnesses		Duodenal Ulcers		Gastric Ulcers		Gastro-duodenal Case other than Ulcer	
		No	Per cent	No	Per cent	No	Per cent	No	Per cent
IN-PATIENTS									
Male	2,507	235	9	65	3	31	1	139	5
Female	2,374	330	14	56	2	62	3	212	9
OUT-PATIENTS									
Male	3,270	312	10	33	1	16	0.5	263	8
Female	5,759	625	11	21	0.4	98	2	503	9

If we analyse the above table it is seen that there is very little percentage difference in ward and out-patient department cases showing gastro-duodenal illnesses, but there is a marked difference in the percentage of duodenal and gastric ulcers in both sexes. In taking a rough estimate of a five years' period (1919-24) in an upper middle-class general practice I find that the clinical incidence of duodenal and gastric ulcer falls below 1 per cent in both classes and in both sexes. It seems, therefore, that if we judge by hospital ward records alone our estimate of the incidence is much too high. If hospital necropsy records are examined the same high incidence prevails, because the necropsies are undertaken where there is a preceding high incidence of serious illness. The relative frequency of duodenal to gastric ulcers as found at necropsy has been fully worked out by Stewart¹ on 602 necropsies, where he gives the percentages as duodenal 6.8, gastric 5.15 and also by Hart² whose figures are duodenal 4.6, gastric 7.13. I think clinically, we must accept figures which are much lower if we are to arrive at an estimate of the incidence in the general population.

SOME ETIOLOGICAL FACTORS

I do not intend going minutely into the etiology of duodenal and gastric ulceration but will give some of the data which have been obtained from the survey of the 214 hospital ward cases.

Age.—It is obviously difficult to assess this etiological factor with any degree of accuracy. The age of the patient when admitted to hospital must not be taken because there is generally a comparatively long history to be considered. Even in carefully recorded clinical histories it is impossible to say that we have elicited the very first symptoms of onset, and, even if we have, the ulcer may

have been there without symptoms For statistical purposes I have taken the age at the onset of symptoms

TABLE II—Age at Onset of Symptoms

Decade.	Males	Females	Total
0-10	None	None	None
10-20	3	9	12
20-30	32	35	67
30-40	20	31	51
40-50	25	29	54
50-60	7	10	17
60-70	8	4	12
Over 70	1	None	1

These figures agree more or less with those of other observers—for example, Fenwick,³ C F Martin,⁴ and Wilhkg and Mignel.⁵

Occupation—I can find no statistical evidence to support the general view that cooks, domestic servants, and glass and porcelain workers show a proclivity to chronic ulcer. The occupations in this series of cases were extremely varied, the incidence being highest amongst miners, but this is explained by the fact that the patients in the Glasgow Royal Infirmary are largely drawn from a mining area.

Alcohol—In 28 male and 6 female cases there was a history of alcoholism (16 per cent), but such a percentage is no higher than obtains in other diseases. Other observers have found much higher percentages, particularly Tourette,⁶ who puts the figure at 55.5 per cent. Alcoholism is certainly a factor in preventing the healing of an ulcer once formed, but whether it is more than a predisposing cause in its production is doubtful.

Trauma—It may be accepted that internal injuries to the stomach mucosa predispose to the formation of an ulcer, and in such a category I include injuries inflicted by chemical poisons and irritating articles of diet, but the statistical information given here more concerns external trauma. In this series there was a history of definite epigastric injury in 10 males (10.4 per cent) and 9 females (7.6 per cent), and the onset of symptoms developed immediately after the injury. Bolton⁷ considers the condition rare, but a percentage of 7-10 can hardly be considered rare. It can be argued certainly that the ulcer was there previously, but clinically we must accept clinical facts. The view that trauma has a place in etiology is upheld by Fenwick.⁸

Heredity—Unlike most other writers I am inclined to believe that heredity plays a part in the production of ulcer, but suggest that it is hereditary habits rather than hereditary tendencies which determine the ulcer. There were 8 male patients (8.4 per cent) and 15 female patients (12.7 per cent) who gave a history of ulcer in one or both parents, and in all these cases one or more brothers or sisters were similarly affected.

Diet—That certain types of diet may cause or predispose to the production of a chronic ulcer is indisputable, but more important than the type of diet is, I think, the regularity with which meals are taken. One generally finds that patients with a chronic ulcer give histories of irregularity of meals, which as a rule are hurriedly taken under bad conditions and in uncongenial surroundings. 75 male patients (78 per cent) gave histories of hurried meals at irregular hours, and 35 of them (36 per cent) had to carry meals to their work, 70 female patients (59 per cent) gave similar histories, and 30 of them (25 per cent) had to partake of carried meals.

Teeth—The condition of the teeth influences many diseases, but in the production of chronic ulcer decayed teeth are a potent factor, and statistical evidence upholds this view. Whether it is the septic condition of the mouth or the consequent lack of mastication it is difficult, or impossible, to state. The condition of the teeth in this series was as shown in Table III.

TABLE III

Condition	Male		Female	
	Number	Percentage	Number	Percentage
Bad	73	76	92	78
Fair	3	3	6	5
Good	29	21	23	17

Syphilis—Many French authors hold that practically all ulcers are syphilitic, but, in this country at any rate, this statement cannot be accepted. In this present series a positive Wassermann reaction was obtained in 8 males (8.4 per cent) and 2 females (1.7 per cent). That syphilis undermines the health and, like other lowering diseases, renders the patient more vulnerable to illnesses of all kinds can hardly be gainsaid, but it cannot be considered a cause of chronic ulcer, and even a positive Wassermann reaction does not necessarily mean that the ulcer is syphilitic. That syphilis of the stomach does exist is undoubted, as McNee⁹ has shown pathologically, and as I¹⁰ have recorded clinically.

Infections—There is no evidence that any one infectious or septic disease more than another causes chronic ulcer. In this series nearly all these diseases were present in one patient or another, the greatest percentage (7.8 per cent) recording a serious influenza. One noteworthy point is that most of the patients (74 per cent) had suffered from a severe infectious or septic disease a short time before the onset of gastric or duodenal symptoms. I refer to such diseases as small-pox, enteric fever, typhus, influenza, malaria, appendicitis, parotitis, and pericostitis. From this it is quite a plausible inference that the local infection of the gastric or duodenal mucosa was the result of one of these diseases.

Other Diseases—Many other diseases are recorded in the histories—as, for example, nephritis, bronchitis, and asthma—but they are, I am sure, of little or no etiological significance. The consideration of anaemia has been left out purposely, because it is impossible to decide whether the anaemia is cause or effect. The same is true of constipation. There is no doubt, however, that anaemia and constipation influence the course of the disease.

SOME OBSERVATIONS ON SYMPTOMATOLOGY

This is not intended to be an exhaustive communication regarding the symptoms of gastric and duodenal ulceration, but merely the percentage incidence of the more cardinal symptoms.

Pain—Of all the symptoms of chronic ulcer of the stomach and duodenum this is the most important. The degree of pain matters little, and the description of it still less. Mild pain creating little general disturbance is as common as agonizing pain which renders the patient unfit. The sensation of pain is variously described as stabbing, gnawing, stinging, aching, sharp, burning, tearing, cramp-like, dull, heavy, grinding, screwing. The all important point with regard to pain is its periodicity, and this was noted in 93 per cent of the total male cases, and in 92 per cent of the total female cases. Sometimes complaint of constant pain is made, and it is in such cases that a careful scrutiny of the whole clinical history must be made to elicit whether or not constant pain was preceded by periodic pain. Equal care must be taken in investigating pain in the back. In such cases the pain has altered in character by reason of adhesions to surrounding structures at the site of the ulcer. These facts are elaborated by Moynihan,¹¹ who describes the sequence of pain in gastric ulcer as food, relief, pain, relief, and in duodenal ulcer as food, relief, pain. This is probably not true in every case, because the duodenal type is simulated by ulcers of the lesser curvature and sometimes of the pyloric antrum. Rosenthal¹² holds that hunger pain is present in about 50 per cent of lesser curvature ulcers.

Vomiting—Next to pain this is, according to percentage incidence, the most important symptom in gastric ulcer, but not of so great importance in duodenal ulcer. Here also the history has to be carefully examined, and to be of diagnostic value the vomiting must bear relationship to the pain, if present, or to the taking of food. The typical history is that vomiting takes place at the crisis of pain, which is thereby relieved. Vomiting was complained of in 81 per cent of male cases and in 85 per cent of female cases diagnosed as gastric ulcer. This is only slightly less than Broster¹³ records—namely, 88 per cent. In duodenal ulcer a very different state of affairs obtains, and vomiting was present in only 16 per cent of male cases and 29 per cent of female cases. Broster¹³ does not give the incidence in duodenal ulcer, but states the incidence collectively with non-ulcer cases as 50 per cent, and remarks that Walton's

observations record only 8 per cent of duodenal ulcer cases which show vomiting.

Haemorrhage.—The vomitus may contain blood admixed with the gastric contents, either in small quantities or as frank haematemesis. In this series blood in the vomitus was found in 35 per cent of male cases and 66 per cent of female cases, and was confined to gastric ulceration only. This is higher than the observations of Crohn¹¹ who states that roughly one-third of the patients vomit blood. The percentage of cases showing haematemesis varies greatly in the records of different observers, and I think this is due to a differing interpretation of the word. If we accept haematemesis as meaning the vomiting of blood, then the percentage given above is what is required, but if we interpret haematemesis as the presence of frank bleeding from the stomach with vomiting then the figures have to be revised to 29 per cent of male cases and 52 per cent of female cases. As already stated, this symptom was present in gastric ulceration only. This is somewhat higher than the figure recorded by Broster¹²—namely 30 per cent. A point worthy of note is that in the male cases haematemesis occurred irrespective of age, while in the female group there was a marked proclivity to it at or about the menopause.

Melaena.—Melaena is not a common symptom of gastric ulcer, as it only occurred in 10 per cent of male and 13 per cent of female cases. In duodenal ulcer the percentages were found to be 55 in males and 57 in females. This is higher than Broster's¹² figures which work out at a percentage of 9.8 in gastric ulcer and 21.2 in duodenal ulcer. These figures would be somewhat higher if cases of doubtful melaena were included. Relfish¹³ considers that the number of haemorrhages from duodenal ulcers is comparatively small and in his opinion Movshian's¹⁴ percentage of 70.6 is very much too high. The diversity of views as to what constitutes melaena may be responsible for the widely differing percentages recorded.

Periodicity.—The periodicity of pain with regard to meals has already been mentioned, but equally important is the periodicity of attacks of gastric and duodenal disturbance. This is common to almost all the histories and need not be given in percentages. Short attacks of ill health separated by long periods of well-being gradually give place to long spells of ill health and shorter periods of well-being until the patient becomes more or less always ill.

Many other important symptoms and signs come into the diagnosis of gastric and duodenal ulceration, but it is of little importance to classify them statistically, so they have been purposely excluded from this review which is primarily a statistical one.

AFTER-HISTORY OF ALL CASES

Considerable time has been spent in getting in touch with the patients who were treated in the wards but by writing personal visitation to their homes, and communications with their doctors, I have succeeded in following up all the female cases and 80 of the 86 male cases. In most of the tables which follow the word "cure" is used. I am fully aware of the criticism which may be levelled at this choice of a word, so I will define my meaning. "Cure" means the disappearance of gastric or duodenal symptoms, and the return of the patient to a state of well-being, maintained in this series over a period of five to fifteen years. If one takes the hospital ward records immediately after treatment a very erroneous conclusion is arrived at

I even realize that a period of five to fifteen years is inadequate in some cases to record a cure, as recurrences not infrequently take place after intervals of well-being extending over such a period. As long as the patient lives one must realize the possibility of recurrence. In compiling statistics of cure the shorter the period after treatment the better the results will appear.

The following table gives the immediate results of treatment and the state of health of the patients when they left hospital, and includes both gastric and duodenal ulceration.

TABLE IV

State of Health	Males		Females	
	Number	Percentage	Number	Percentage
Cured	64	67	89	76
Improved	21	22	17	14
Failures	3	3	3	2.5
Irregular dismissals	6	6	3	2.5
Deaths	2	2	6	5

From this table it is seen that the majority of patients left hospital cured or improved. The average period of treatment extended to forty-three days. These results correspond more or less with the figures given by Lenbe¹⁵ in a series of 424 cases. In later statistics¹⁶ of 627 cases he shows a higher percentage of cures—namely, 90 per cent.

If the foregoing table is more critically dealt with in respect of the duration of symptoms prior to the patients coming under medical treatment, we get a better idea of cure in relation to chronicity of symptoms.

It is clear from the figures given in Table V that the immediate result of medical treatment is extremely good, especially if the symptoms have not been present for more than one year (Group I). It is however, into Group II that most of this series fall, and there is a distinctly smaller percentage of "cured" cases. In Group III the total number of cases is small, but it has to be noted that the percentage of cases "cured" has fallen to a very low level indeed. It is to be noted that the "improved" percentage rises as the "cured" percentage falls, except in the case of the males in Group III. I attribute this to the fact that more male patients seek operation than female patients, and consequently in the column of "failures" in Group III there is a high percentage of male "failures". This is due to the larger number of male cases going to the surgeon, and I have considered them as "failures" because, strictly speaking, a case which is operated on is a medical failure. I have considered irregular dismissals and have not eliminated them when calculating percentages because I think a more accurate figure is thus arrived at. One of the most striking observations is the "deaths" column, which shows that the shorter the history the greater the percentage of deaths. This is explained by the fact that profound haematemesis is liable to occur in the more acute cases and so cause a higher death rate, but I am also of opinion that cases which show active haemorrhage have a distinct tendency to heal quickly and thus to some extent explains the high percentage of "cured" cases in Group I.

TABLE V

Duration of Symptoms	Cured				Improved				Failures				Irregular Dismissals				Deaths			
	Number		Percentage		Number		Percentage		Number		Percentage		Number		Percentage		Number		Percentage	
	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F
I. Less than one year male 43 female 5	25	36	83	84	1	2	3	5	0	0	0	0	2	0	7	0	2	5	7	11
II. One to ten years 63 female	37	50	64	79	18	10	31	16	1	1	2	2	2	1	3	2	0	1	0	2
III. Over ten years 12 female	2	3	25	25	2	5	25	42	2	2	25	17	2	2	25	17	0	0	0	0

Nielsen¹⁹ has made observations on the result of treatment in relation to duration of symptoms, and compiles them as follows

TABLE VI

Duration of Symptoms	Cured	Improved	Unimproved or Operated upon
I Less than one year	93	7	—
II One to ten years	63	17	20
III Over ten years	40	25	35

Although he has not differentiated the sexes, or included deaths, the figures in the main agree with this series

It is of interest to review at this stage the condition of patients at the end of a 5-15 year period, and for that purpose I have compiled the results in much the same manner as in Table IV. All cases which have been treated surgically after discharge from hospital are included in "failures," and some of the deaths have followed surgical intervention. The percentages are calculated on the original number of cases

TABLE VII

State of Health	Males		Females	
	Number	Percentage	Number	Percentage
Cured	28	29	47	40
Improved ..	14	15	24	20
Failures ..	30	31	29	25
Lost trace of ..	6	6	0	0
Deaths	18	19	18	15

If Tables IV and VII are compared it will be observed that the immediate results are much more encouraging than the late results, and that many of the "cured" and "improved" patients in the former table find themselves among the "failures" in the latter. This conclusion has been arrived at by other observers. Russell⁹ reports on a series of cases two to three years after treatment, and records 27.7 per cent cured and 14.9 per cent improved. In France Delmasure²¹ finds the percentage even lower—namely, 14 per cent well, 23 per cent improved, 29 per cent recurrences, 25 per cent operated upon. Forman,²² in a gastric ulcer series, five to thirteen years after, records 22 per cent cured, 20 per cent improved.

I have not compiled any table to compare with Table V because it is evident that the greatest number of patients who remain cured come from Group I—that is, where symptoms have been present for less than one year.

Although this paper is primarily intended to show the after-results of medical treatment, it is interesting to dissociate cases treated surgically from those treated medically. In this series the number of cases treated by the surgeon is much too small to allow of any definite conclusion being drawn. It has also to be remembered that the cases which have gone to the surgeon are medical failures.

TABLE VIII

Sex	Lost trace of		Treated Surgically		Treated Medically	
	Number	Percentage	Number	Percentage	Number	Percentage
Males	6	6	23	24	67	70
Females	—	—	9	8	109	92

The following table indicates the after-results of surgical and medical cases, and the percentages are based on

23 male and 9 female surgical cases, and 67 male and 109 female medical cases respectively

TABLE IX

State of Health	Surgical				Medical			
	Male		Female		Male		Female	
	No	Per cent	No	Per cent	No	Per cent	No	Per cent
Cured ..	10	44	4	45	28	42	47	43
Improved ..	2	9	1	11	14	21	24	22
Failures ..	4	17	2	22	14	21	22	20
Deaths	7	20	2	22	11	16	16	15

These figures show very little percentage difference except that in the medical group there are more cases improved and fewer deaths. The majority of surgeons show a much better percentage of cures, but they deal with series of cases not confined to medical failures, and in most instances a more immediate survey of post-operative results. Paterson² shows excellent post-operative results over a 1-10 year period, but in the lifetime of a gastric patient a decade is a short space of time.

Condition of the Patients with regard to Work

I have here calculated the percentage on the original number of patients treated surgically and medically

TABLE X

	Surgical				Medical			
	Males		Females		Males		Females	
	No	Per cent	No	Per cent	No	Per cent	No	Per cent
Unable to return to any work	4	17	2	22	14	21	21	19
Returned to work but gave up or changed to lighter occupation	3	13	1	11	11	16	13	12
Returned to original occupation	9	39	4	44	31	46	59	54

The capability of returning to work in the case of women was in many cases estimated by their ability to return to their ordinary household duties, such as washing, scrubbing, etc. Where they found it necessary to get outside help for rough work they were considered to have changed to a lighter occupation, and when they could not do light household dusting, washing dishes, etc., they were considered as unfit for any work.

It will be seen that the percentage of cases able to return to their original occupation is more or less comparable with the percentage of patients remaining "cured," and the percentage of patients unable to return to any work is very similar to the percentage of patients whose symptoms are progressive.

Readmission to Hospital

Many patients gave a history of having had to seek further medical advice for their gastric condition, but the following percentages were readmitted to hospital (any hospital) for further medical treatment. No patient was readmitted to hospital for further surgical treatment, but cases previously treated surgically were readmitted for medical treatment.

TABLE XI

	Surgical				Medical			
	Male		Female		Male		Female	
	No	Per cent	No	Per cent	No	Per cent	No	Per cent
Readmitted to any hospital	2	9	3	33	14	21	26	24

From the above table it will be seen that if we take the readmissions of both sexes the percentage of surgical cases readmitted is about equal to that of the medical cases.

The two male patients who had been surgically treated were readmitted for medical treatment on account of the recurrence of symptoms one and four years respectively after operation. One female patient who had been treated surgically was readmitted three times for recurrence of symptoms which developed one and a half years after operation. The remaining two female patients who had been surgically treated were readmitted owing to haematemesis two and five years afterwards respectively. Both of these patients were readmitted on several occasions. Of the 14 male patients who had been treated medically, 9 were readmitted for recurrence of symptoms one to five years afterwards, and 5 for haematemesis two to twelve years afterwards. Of the 26 female patients who had been treated medically, 16 were readmitted for recurrence of symptoms one to four years afterwards, and 10 were readmitted for haematemesis one and a half to ten years afterwards. Almost all the cases were readmitted on more than one occasion. All patients who were readmitted for treatment gave previous histories of many years' standing.

Deaths

In this series there were 36 deaths distributed as shown in the following table. The percentage is calculated on the total number of cases treated.

TABLE VII

Cause of Death.	Surgical		Medical		Percentage
	Male	Female	Male	Female	Male and Female
Haematemesis	—	—	5	7	5.6
Post-operative collapse	4	2	—	—	2.8
Perforation ..	3	—	—	3	2.8
Carcinoma ..	—	—	1	4	2.3
Cardiac failure	—	—	3	—	1.4
Pulmonary tuberculosis	—	—	2	—	0.9
Cerebral haemorrhage..	—	—	—	1	0.5
Accident ..	—	—	—	1	0.5

The percentage of deaths from haematemesis above recorded is high when compared with that obtained by other observers. Nielsen¹⁹ reports one death in 182 ulcer cases observed for two and a half to nineteen years, and Hurst¹ places the mortality rate at 2.5 per cent in a series of 600 cases from Guy's Hospital.

It will be noticed that post-operative collapse was responsible for death in 2.8 per cent of the total number of cases treated. If the percentage is calculated on the number of cases treated surgically the mortality is 19 per cent. Gastro-jejunostomy was the operation performed in all cases in this series, and for such operative procedure Pannett²³ assesses the mortality at 4.5 per cent. The high percentage recorded above may be due to the fact that the cases treated surgically were medical failures.

Perforation was responsible for 2.8 per cent of deaths amongst the total number treated, and was equally distributed between surgical and medical cases. In the surgical cases it is impossible to state whether the perforation was at the site of the original ulcer or was due to gastro-jejunal ulceration, as no further surgical treatment was carried out.

The percentage of deaths from carcinoma following on chronic ulcer is discussed by Paterson,²³ and coincides with the figure of 2.3 per cent above recorded. In this series the deaths all occur in the medical group, and the estimate may therefore be too high owing to inaccurate diagnosis.

The remaining causes of death are unimportant, as they may be incidental to any chronic illness.

TREATMENT

The treatment of gastro-duodenal ulceration is not intended to form part of this paper, but it may be stated that a more or less intensive alkali treatment with appropriate dietary was practised in these cases, and the remote results are not by any means so encouraging as the immediate results, so that I am not so optimistic about cure as MacLenn⁶ in his recent publication. It will be interesting to see his results in a five to fifteen years' survey.

CONCLUSIONS

1 The incidence of gastro-duodenal ulceration as compiled from hospital ward records is much too high an estimate for the general population.

2 The age at which gastro-duodenal ulceration commences is difficult to determine with accuracy.

3 Biological factors are influenced to a great degree by local conditions.

4 Alcohol, trauma, and heredity are not unimportant factors in the production of gastro-duodenal ulceration.

5 The "carried" meal is responsible for the onset of ulceration in many cases.

6 Infection from bad teeth, and infectious and septic diseases are important factors.

7 Syphilis may cause gastric disease, but not necessarily chronic ulceration.

8 Due regard should be given to the early history of pain.

9 A better understanding should be arrived at with regard to what constitutes haematemesis and melaena, as opposed to the vomiting of blood as coffee-grounds and the presence of blood in the faeces.

10 Haematemesis is a common symptom at or about the menopause.

11 Immediate results are much more encouraging than late results.

12 The cure and mortality rates are markedly influenced by the length of time symptoms have been present.

13 Surgical treatment in medical failures adds to the "cured" list but shows a heavy mortality rate.

14 Capability of returning to work bears a close relationship to the physical state as expressed in gastric well-being.

15 The number of deaths from haematemesis is higher than is usually recorded.

16 The number of deaths from carcinoma following chronic ulceration is about the figure which is generally accepted in Great Britain, but much lower than that accepted in America.

17 Our present methods of treatment are too much centred round healing of the ulcer, and too little attention is paid to investigating the real cause of ulceration.

I desire to thank Professor Walter K. Hunter for allowing me the privilege of making use of his ward records for the purpose of investigating this series of cases.

SECTION OF MEDICINE.

Friday, July 27th

ACUTE NEPHRITIS

DR CYRIL LEWIS (Cardiff) was in the chair for the third session of this Section, and called upon Professor T G Moorhead (Dublin) to open a discussion on acute nephritis.

Professor MOORHEAD dealt first with prophylaxis, and said that since septic tonsils and nasal sinuses might originate a toxin capable of damaging the kidney, surgical attention to these areas might be a preventive measure. Osman's claim that the administration of alkalis in scarlatina diminished the incidence of nephritis was hopeful, though other workers had been less successful. Under the heading "acute nephritis" Professor Moorhead included not only non-suppurative inflammations of the kidney, but also the non-suppurative degenerations which sometimes went by the name "nephroses." After a reference to the symptomatology the speaker discussed the chemistry of acute nephritis, and said that the albumin was generally considered to be blood protein filtered through the glomeruli, but a recent study by Kellaway, Davies, and Williams suggested that with severely damaged kidneys much of the protein came from the kidney cells. In addition to the chloride retention there was frequently a slight acidosis due to a diminution in the sodium carbonate blood content. The changes noted in the cerebro-spinal fluid were a definite increase in the pressure of the fluid, an increase in the urea content, and a considerable increase in the chloride, especially in cases where uraemia threatened. Functional kidney tests in the recovery stage might give valuable help in estimating residual kidney damage. As regards treatment, Professor Moorhead said that he was in general opposed to too long a period of rest in bed. The hot pack and radiant heat were for the moment in disfavour, but, when uraemia threatened, a good radiant bent bath was undoubtedly beneficial. He discussed the value of decapsulation, but did not recommend it. If uraemia supervened venesection was valuable, and great benefit sometimes ensued from lumbar puncture. Morphine was now recognized as safe and satisfactory in checking repeated uraemic convulsions.

Dr H L TIPP described the condition of acute haemorrhagic nephritis, a disease occurring at any age but usually in the young, and in the majority of cases associated with definite disease of the throat, such as tonsillitis and cervical adenitis. In the majority of cases there was no history of previous scarlatina. The characteristic feature was the haematuria, the quantity of albumin corresponding with that of the blood. There was no excess of leucocytes, though a few cellular and granular casts might be found in the early stages. The urine was usually sterile. The classical symptoms of acute parenchymatous nephritis were usually entirely absent. The profuse haematuria subsided in a few days, and in 75 per cent of cases there was a rapid return to normal health with normal urine. As regards the remaining 25 per cent, in 20 per cent the clinical condition was good, but there was a trace of albumin and a few blood cells, further investigation showed that these usually cleared up without serious effects, but a small residuum remained that continued to show red blood cells in the urine and which eventually might pass on to a typical nephritis. In a few cases which had been submitted to operation on a mistaken diagnosis a portion of the kidney removed had shown only the presence of haemorrhages in some of the glomeruli. Although the condition undoubtedly occurred as the result of an infection, he was inclined to look upon it not as a true nephritis, but as due to an increased permeability of the kidneys. In the acute stages simple lines of treatment were quite sufficient, and it was advisable to keep patients under observation until the red cells had disappeared from the urine.

Dr HUGH GAINSBOROUGH drew attention to the importance of acute focal infections in the etiology of acute

nephritis. Gray had recently stressed the importance of streptococci as the commonest causal agent, but other organisms might also play a part. Gray had suggested that the greater sensitiveness of the kidney to circulating toxins might be due to concentration of the toxins in the plasma by the glomeruli. It was possible that even if the original focus of infection cleared up the kidney infection might remain and the nephritis slowly progress. In addition to this infective etiology it must be borne in mind that nephritis could be produced by metabolic disturbances such as the alkalosis of high intestinal obstruction. Although the metabolic disturbances had been chiefly studied in chronic nephritis, they could all be paralleled in acute nephritis. Dr Gainsborough concluded with some observations on the hypercholesterolaemia of nephritis.

Mr R H PARAMORE (Rugby) thought that acute nephritis seemed rather a degeneration than an acute inflammation of the kidney. It usually appeared insidiously, and often was only recognized by the occurrence of oedema, malaise, or cardiac symptoms, which led to an examination of the urine. The degeneration could only be due to a toxin or to an interference with the blood flow through the renal capillaries. Acute nephritis was almost certainly the result of a toxin, and nearly everybody believed that the "neuro-nephritis" of eclampsia was caused in the same way, but there was considerable evidence that the visceral state in eclampsia was produced by mechanical forces incidental to pregnancy, which interfered with the blood flow through the visceral capillaries. The question arose whether mechanical forces played any part in the rise of the acute nephritis in the non-pregnant. In this respect the speaker referred to the occurrence of adolescent albuminuria, and of the albuminuria produced by strenuous exercise in athletes, which was comparable with that produced by labour. Was it possible that an aberrant renal state, determined by such means, was the earliest stage of acute nephritis? Was the epidemic of acute nephritis which occurred during the war determined by the prevalence of micro-organisms or by the arduous physical conditions to which the patients had been subjected? The speaker discussed the causation of anuria, and suggested that the anuria after labour, or after suddenly emptying the bladder in a case of enlarged prostate, could be explained on the assumption that with the sudden fall of urinary pressure felt in the tubules traversing the renal medulla before it could reach those in the cortex a concomitant engorgement of medullary capillaries occurred, blocking or clamping the uriniferous tubules as they emerged from the cortex. The assumption was supported by the effect of decapsulation of the kidney in anuria. The speaker had tried lumbar puncture in a case of eclampsia, and followed it by inducing spinal anaesthesia. The chloroform which was given to stop the fits and allow the lumbar puncture was stopped after the tropacocaine had been injected, no further fits occurred, and the woman recovered. The idea of the procedure was to reduce the tension of the abdominal walls, and thus the compression of the abdominal viscera.

Dr A E GOW pointed out that in considering the possible value of antitoxin on the nephritis of scarlet fever it was necessary to bear in mind that scarlet fever was becoming a much less serious disease, and that comparisons with an earlier form might be fallacious. Scarlet antitoxin was prepared from a horse immunized with streptococci, but the scarlatinal nephritis was generally believed to be due to a virus that accompanied the streptococcus. He thought it was necessary to distinguish between two types of acute nephritis—namely, a diffuse glomerulo-tubular nephritis, and toxic degeneration affecting the convoluted tubules. In the first the urine was always diminished, the specific gravity in the acute stages was normal, haematuria was apt to persist, and casts were always present, particularly of the epithelial variety. In the second type the quantity of the urine was little altered, the specific gravity was often low, and casts were less numerous, the blood and leucocyte casts predominating, in this type also organisms were frequently to be found in stained films, although they did not grow in cultures. In the absence of facilities for more complicated investigation much information could be gained from examination of the urine alone, if it was of normal quantity and good colour,

and the specific gravity of a twenty four hour specimen was not below 1015, the kidneys could not be seriously damaged.

Dr R I MACKENZIE WALLIS defined two distinct types of renal disease associated with scarlatina (1) the toxic type, and (2) the true acute glomerulo-tubular nephritis. The first type was met with in the first few weeks, and might show no clinical evidence of disease during life, although the necropsy revealed all the characters of an acute nephritis. In the early stages of the second type the urine contained albumin in quantity and often red blood cells, hyaline casts, and leucocytes, which were a constant feature, the urine in this type was always sterile. For diagnosis he relied on the estimation of the blood urea content and the diastase content of the urine, examination of the urinary protein also served to differentiate the types. Their value was well seen in eclampsia, with its low blood urea, raised urinary diastase, and relative excess of globulin. Dr A F S SLADEN (Swansea) agreed with the views expressed by Professor Moorhead on the status and value of chemical analysis in nephritis, that these were inevitably auxiliary only to the clinical investigation of the case. The importance of excretion of fixed ammonia in the urine was emphasized for its value in prognosis and for its possible value in elucidating the finer differentiation of disturbances of function in the kidney.

The CHAIRMAN, closing the discussion, spoke of cases of idiopathic haemorrhage which had come under his notice on the operating table in his capacity as anaesthetist, and alluded to two cases of haemorrhagic nephritis associated with sepsis as the probable etiological factor.

SECTION OF SURGERY

Friday, July 27th

PANCREATITIS

PROFESSOR A W SHEEN, President of the Section, took the chair and called upon Mr Geary Grant to open a discussion on pancreatitis.

Mr GEARY GRANT (Cardiff) dealing with acute necrosis of the pancreas, commented on the part played by the presence of powerful ferments and anatomical variations of the ducts. There were three main etiological theories (1) that acute necrosis was due to embolism of the pancreatic arteries or thrombosis of the pancreatic veins, (2) that the infection came by way of the lymphatics from the gall bladder, (3) that the condition was set up by the regurgitation of bile into the pancreatic ducts. The experiments in support of the last theory were discussed. Acute necrosis of the pancreas had occurred from the passage of an ascaris up the duct of Wirsung carrying with it duodenal contents; it had also followed certain abdominal operations when the pancreas was injured. Failure to make a pre operative diagnosis was often due to forgetting the pancreas similar symptoms and signs were present in other acute abdominal diseases. The speaker maintained that cases of acute cholecystitis and empyema of the gall bladder should be regarded as surgical emergencies. He thought that drainage of the affected portion of the pancreas, gauze tamponade to wall off the peritoneum, and drainage of a distended gall bladder were the best lines of treatment. The gland should not be incised.

Mr DIOSY CHAMBERLAIN (Leeds) thought acute pancreatitis was possibly more common than was realized, since probably some cases were of a subacute type and the patient recovered without operation. He had performed bacteriological examinations of bile from the gall bladder in four cases and recovered a haemolytic streptococcus though the gall bladder appeared normal. The cyanosis associated with the disease was probably attributable to respiratory causes and not to septicaemia, since it occurred in some cases of perforated gastric ulcer. He thought that the diastatic index afforded the only reliable test, and that on opening the abdomen the discovery of blood stained fluid was diagnostic. Mr Chamberlain thought that lymphatic infection, usually from the gall bladder, was the cause of the disease. The pancreatic duct opened into the common bile duct obliquely, and the valvular septum between them prevented regurgitation up the pancreatic duct when there was an increased

tension in the common bile duct. The treatment was to drain the gall bladder, posterior drainage of the pancreas (the natural method), and drainage of the pelvis, if necessary. Drainage of the lesser sac could be effected by removal of the eleventh rib in the left mid axillary line, but the state of the patient would seldom permit this. Painting the abdominal skin with an ethereal rubber solution protected it.

Dr R L MACKENZIE WALLIS discussed methods of diagnosis. In 1920 he had concluded that there was no test pathognomonic of pancreatic insufficiency, that the association of increased diastase content of the urine with the Loewi adrenaline hydriasis test, and the presence of glycosuria, afforded strong evidence that the pancreas was at fault, and that if there was in addition creatorrhoea and stentorrhoea the suspicion of pancreatic insufficiency was confirmed. The results of further investigations had tended to confirm these conclusions. In acute pancreatitis the association of glycosuria with cyanosis was important since it denoted fat necrosis, which, in his opinion, was the cause of the cyanosis. The "fleeting" character of these tests must not be overlooked, especially as regards the urinary diastase content and the glycosuria. Variations in the urinary diastase were ascribed to attacks of subacute pancreatitis, and the same applied to the presence of glycosuria. In inflammatory conditions of the pancreas of a more chronic type these tests had proved of value. The diastase content was not usually so high as in the acute form, but in some cases of catarrhal pancreatitis it might be raised. Catarrhal pancreatitis, in his experience, was common, and due to infection of the pancreas. In chronic pancreatitis there was usually considerable interference with the external secretion of the pancreas, and creatorrhoea and stentorrhoea were of common occurrence. A complete chemical examination of the urine and stools would provide important data, and duodenal intubation was a valuable aid in diagnosis. Failure to obtain results might be due to the tests being applied when the disease had so far progressed that the pancreas was functionally inactive. Tests for occult blood were particularly valuable in cases of chronic pancreatitis; they were consistently negative, whereas in carcinoma of the pancreas positive results were found in every case. Chronic pancreatitis was a common disorder of digestion, not only was it found in diseases of the gall bladder, duodenum, and stomach, but also in infections of the alimentary tract. About 80 per cent of the sprue cases showed evidence of an associated chronic pancreatitis, and the same was true of coeliac disease. Another point was the frequent occurrence of this condition in mental patients; this observation was of particular interest, since a Greek physician, Endermus, in 25 B.C., described the pancreas as supplying a digestive secretion and also playing a part in the control of mental disorders. Digestion necrosis following the drainage of the pancreas could be combated successfully by repeated application of horse serum to the abdominal wound. This adsorbed the ferments and removed them from the sphere of action.

Professor A W SHEEN (Cardiff) asked whether there was any relation between pancreatitis and parturition as he had had a case following childbirth. A rapid pulse was a very noticeable feature of the acute disease.

Mr F C PRYDS (Newcastle-on-Tyne) mentioned the wide range of inflammation between mild cases which recovered naturally and the acute haemorrhagic type. Recovery was possible even after sloughing and discharge of most of the gland. He stated that pancreatitis had a sufficiently definite symptomatology to make it fairly easily diagnosable. The important symptoms were severe epigastric pain, pain referred to the back and to either scapula, cyanosis, and a rapid pulse. He advised drainage of the gall bladder and also of the pancreas at the site of greatest damage. It was worth while remembering the possibility of acute pancreatitis in cases presenting symptoms much more severe than the signs and in cases with anomalous gall bladder symptoms.

Professor BROSS (Manchester) said that the mortality rate of acute pancreatitis in Manchester during the four years 1924-27 was 28.5 per cent. The disease was commoner in the female than in the male, but the mortality in the latter was much higher. Pancreatitis of a mild degree was much more common than was realized. Continued

severe pain and a sustained rapid pulse were important points in diagnosis. The cyanosis present was due to impaired action of the diaphragm. In desperate cases the overlying peritoneum was incised and drainage of the pancreas alone was effected. Any definite area of softening present was incised. When the patient's condition permitted, drainage of the gall-bladder or common bile duct should be arranged. The regenerative power of the pancreas was often surprisingly good.

Professor FULLERTON (Belfast) agreed that the pain was severe, but usually generalized, pain in the back was not always present. The pulse was generally very rapid, but cyanosis had not been a marked feature in his cases. He drained the gall-bladder and pancreas, but did not incise the latter. He did not place a drainage tube near the duodenum owing to the risk of ulceration into this portion of gut. He had a case in which a very large portion of the pancreas was extruded, but there was no evidence of pancreatic insufficiency. He had performed partial cholecystectomy and then performed an anastomosis with the stomach or duodenum. Mr BROCKMAN (Sheffield) thought that probably the explanation of the cyanosis was a chemical one, and that suprapubic drainage alone was less likely to be followed by fistula. The gall-bladder should also be drained. Mr A WILFRED ADAMS (Bristol) reported a case of this disease following parturition. In another case acute pancreatitis had followed an injury, and the speaker suggested that some cases might be of traumatic origin.

Mr GEARY GRANT, replying, said that he had seen three cases following parturition. Severe pain was absent in one case and the abdomen was not rigid. Rapid pulse was the rule, but cyanosis was not common. He did not agree with Mr Chamberlain that the presence of blood-stained fluid was diagnostic, since it occurred in other abdominal diseases, such as torsion of the omentum. The patient with acute pancreatitis would rarely stand posterior drainage.

DIAGNOSIS OF URETERIC CALCULI

Professor ANDREW FULLERTON (Belfast), in opening the discussion on the diagnosis of ureteric calculi, said that in 80 per cent of his cases the chief constituent had been calcium oxalate. These calculi were irregular and presented sharp projections which produced slight haemorrhage and arrested the passage of the stone. The pain was caused by irritation of the mucous membrane, increased peristalsis of the ureter, and increased tension in the renal pelvis. Reflex polyuria occurred with diminished specific gravity of the urine in 70 per cent of his cases. This unilateral diuresis could be observed through the cystoscope, and the specific gravity tested on fairly small quantities by means of glass beads. This diuresis and also calculous anuria could be explained by reflex stimulation of the vaso-constrictor or vaso-dilator fibres to the blood vessels of the kidney, a strong stimulus set up vaso-constriction and anuria, and a milder stimulus caused vasodilatation and diuresis. The site and character of the pain gave no clue as to the size and position of the calculus. Pain, fixed or radiating, in the right iliac fossa was often mistaken for appendicitis, and the speaker emphasized the point that there should be a careful examination of the urine, especially for microscopic blood, before chronic appendicitis was diagnosed and treated. The ureter should be examined retroperitoneally if the appendix and other abdominal organs were found to be normal at operation. Frequency of micturition and dysuria might be absent, and rectal tenesmus might be present when the stone was in the lower ureter. The presence of a small quantity of blood in the urine was of more importance than the discovery of a few pus cells. Radiography was a very valuable aid to diagnosis. Stereoscopic photographs were often useful. Professor Fullerton showed some excellent x-ray photographs of specimens of stones, and he also described the cystoscopic appearances in cases of ureteric calculi.

Professor E. B. C. MAYNDS (Belfast) said that chemical analysis of the urine seldom failed to distinguish the affected from the normal side. The urine from the affected side was usually less concentrated, but chemical methods were more sensitive in detecting this change, and were

valuable in estimating the degree of damage to the kidney cells. The biochemical problem was to distinguish between reflex diuresis and the loss of power of concentration due to damage of the renal epithelium. In the reflex diuresis the ratio of chloride concentration between the affected and unaffected kidneys should be greater than the corresponding ratios of urea, phosphate, and creatinine, the degree of chloride concentration depended upon the relation between the chloride concentration on the normal side and the concentration in the blood plasma. The ratio of urea concentration between the affected and normal side should be somewhat higher than the corresponding creatinine ratio. In renal failure there was loss of power of chloride concentration. It might be possible to develop a renal efficiency test on these lines.

Dr HUGH YOUNG (Baltimore) agreed that calcium oxalate was the commonest constituent. Inflammation of the seminal vesicles and prostate sometimes gave rise to pain referred to the back, just as with ureteric calculus. Rectal tenesmus, sexual pain, and pain on micturition occurred when the stone was in the lower end of the ureter. Stereoscopic photographs were very valuable for the exact orientation of a shadow. A ureterogram, by the presence of a negative shadow, would show the presence of a ureteric calculus when this was invisible on the x-ray plate.

Mr KENNETH WALKER said that the pain was very similar in ureteric and renal calculi, and probably distension of the renal pelvis caused it in each case. When x-rays were negative the wax-tipped bougie could be used to prove the presence of a stone. Diagnosis of a ureteric stone must always include investigation of the condition of the ureter and kidney. He had met with several cases of ureteric calculi which had previously undergone an operation for appendicitis. Mr SWIFT JOLY said that an increased flow from the affected side could often be seen on cystoscopy. Symptomless pyuria was more often due to a silent stone than to any other cause. Ureterograms obviated the use of stereoscopic radiograms in the diagnosis of ureteric stone. Mr J. B. MACALPINE (Manchester) exhibited some photographs, including a ureterogram demonstrating the presence of a stone which was not shown on x-ray examination. He pointed out that the normal ureter could be easily displaced by the catheter, but peritonitis at the site of a calculus fixed the ureter.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Friday, July 27th

ACUTE CONDITIONS IN THE LOWER ABDOMEN

The final session of the Section of Obstetrics and Gynaecology was given up to the reading and discussion of short papers.

Professor W. W. CHIPMAN (Montreal), dealing with acute conditions in the lower abdomen, emphasized that in the female genital tract there was direct communication between the contaminated skin surface and the peritoal cavity. This explained the frequency of pelvic infections. To open or not to open the abdomen was a question of the gravest importance. He strongly objected to the term "giving the patient the benefit of an exploration", it was not a benefit to the patient. A vaginal examination and a rectal examination must be an invariable preliminary. Emergencies consisted of haemorrhages, acute infections, obstructions, strangulations, and thromboses. The history of the onset often accorded the clue to the diagnosis. A catheter should always be passed. Pain was always the outstanding symptom, but the abdomen should never be opened for pain only without other symptoms. Much information was obtained from the face, and in acute cases movement was a torture. Haemorrhage was commonest from a ruptured tube, but might be very severe from other sites—for example, rupture of a Graafian follicle. He described the common symptoms of tubal rupture. In the chronic cases diagnosis might not be so easy. The degree of anaemia and high leucocyte count might point the way. He practised a preliminary exploratory colpotomy if blood were found, he then opened the abdomen. The differential diagnosis between acute appendicitis and acute salpingitis was difficult and of the greatest importance from the point of view of

surgical intervention. In salpingitis the temperature might be higher but the pulse rate not correspondingly raised, the patient did not appear so ill, and intestinal disturbance was not so great. Signs of a gonorrhoeal infection should be sought for, a fixed painful uterus pointed to tubal trouble. He was strongly against operating on the tubes in the acute stage. A history of previous attacks, the onset with unilateral pain, pointed to the appendix as the seat of the trouble. The common seats of strangulation were ovarian cysts and fibromyomata. He uttered the warning that if the onset was accompanied by a chill or a rigor the probable cause was pneumonia with infection spreading below the diaphragm. A ureteric stone might be mistaken for an acute abdominal condition.

ACUTE PELVIC CONDITIONS

Mr FREDERICK WILLIAMS followed with a communication on the acute pelvis. He grouped cases into those presenting symptoms of fever and those with symptoms of shock. Prosalpinx and salpingitis would appear to be a protective mechanism against widespread peritonitis. Acute primary pneumococcal peritonitis might simulate in the early stages acute salpingitis. Focusing the attention upon the whole genital tract would generally disclose some lesion or lesions which should differentiate salpingitis from appendicitis. The new tests adopted to aid in the diagnosis of tubal rupture had proved disappointing in practice. The treatment of ectopic pregnancies by salpingectomy or salpingostomy was still an open question. His experience suggested that the importance of the urgent symptoms accompanying torsion of an ovarian pedicle had been exaggerated. The need for a thorough examination of the whole abdomen and the necessity for an adequate abdominal incision when an operation was performed were the two points he wished particularly to stress.

Mr RIVETT referred to the rarity of bowel infections in the genital tract. He was an advocate of early operation in acute tubal inflammations. It had not been demonstrated why, if delay was justifiable in salpingitis, it should not be equally justifiable in torsion of an ovarian cyst.

Professor HENDRY (Glasgow) deprecated operating upon acute salpingitis. Conservative treatment was frequently followed by complete functional recovery. He had found the blood sedimentation test of value in deciding when to operate in active inflammatory conditions of the pelvis. Delay of some hours' duration was permissible if there was much shock in torsion of an ovarian cyst.

Dr GRAY WARD (New York) said that in America it was felt very strongly that operation was not justified in the acute tube. Very many were restored to complete functional activity by expectant treatment. The appendix could easily be dispensed with, the tubes could not.

Mr ANTHONY GILES was impressed with the realization that gynaecology was the interpretation of physical signs in the light of the case history. An accurate diagnosis could not be made on the one without the other. He condemned buttonhole incisions in the abdominal wall; the pelvis should always be examined in operating on the appendix. The risk of operating on the acute tube was much greater than when inflammation had settled down. They could not regard appendicitis and salpingitis as analogous cases. He thought that the earlier operation was performed on cases of torsion of an ovarian pedicle the better.

RADIUM THERAPY IN CERVICAL CARCINOMA

Dr GRAY WARD (New York) read a paper on radium therapy in carcinoma of the cervix uteri, based upon an analysis of the results obtained at the Women's Hospital in New York. The question was whether the results of radium therapy could be compared with those of Wertheim's operation without the primary mortality of the operation. He referred to the Ministry of Health report compiled by Dr Janet Lane-Claydon. They had not a large quantity of radium available at the Women's Hospital. The employment of massive doses had no better results than frequent dosage with small amounts. Constant personal contact between patient and surgeon was of the utmost importance. Fifty per cent of their cases had more than one irradiation. They attributed whatever success they had to the strict follow up of all their patients. They

employed a simple technique, which he described and illustrated. Blood transfusion was an important adjunct in combating anaemia and septic absorption. They had not employed high voltage x-ray therapy as a routine in addition to radium as they had not yet installed the apparatus. They had found the insertion of a self-retaining catheter a great addition to the patient's comfort. He showed some very striking colour drawings illustrating the actual changes undergone by the growth as the result of radiation. They had not found that the presence of any particular type of cancer cell was of any value from the point of view of prognosis. Of all cases treated 23.1 per cent were living at the end of five years. Of cases limited to the cervix—that is, operable cases—53.1 per cent were alive after five years. The lack of standardization in the classification of cases had caused a great deal of confusion hitherto, only five-year results should be considered. Cases not traced should be regarded as dead. He pleaded for the immediate repair of cervical lacerations. Their results showed that radium was preferable to operation in all cases of cervical cancer.

Dr E. FARQUHAR MURRAY (Newcastle), discussing the radium treatment of carcinoma cervicis and intractable menorrhagia, quoted statistics from his own practice. In carcinoma he thought that radium was most valuable, and that in certain cases it could produce results little short of miraculous. He thought it was certainly the only treatment of proved value which could be used in the majority of cases met with. Whether it had superseded the radical operation when such was possible he was still somewhat doubtful. In the treatment of menorrhagia radium gave the most encouraging results. All cases where a satisfactory technique had been employed gave excellent results. Its use in cases complicated by small fibroids was only justified when intercurrent disease contraindicated hysterectomy. He suggested that radium might be of use in producing an artificial menopause in cases suffering from blood diseases, in order to conserve their blood supply.

Dr MAEVL RAMSAY (Plymouth) agreed with the attack on Wertheim's operation. The technique of radium therapy could be acquired by anyone of ordinary skill. The disadvantage of a Wertheim operation, even when done by the greatest expert, was the subsequent contraction of the scar in the pelvis, which caused much discomfort to the patient. Dr BADEN had not yet brought herself to use radium in operable cases on account of the inaccessibility of the glands to its effects. The advisability of using radium in menorrhagia was not obvious to her on account of the risk of creating an artificial menopause in young women. Major GOSFRET (Calcutta) was impressed by the perfect follow-up system in Dr Gray Ward's hospital in New York. He contrasted methods followed in New York, Vienna, and in this country. He spoke of the application of iodine in the detection of very early cases of cancer. Following Wertheim's operation there was frequently cystitis due to injury to the bladder. Dr HALL (Newcastle), speaking as a general practitioner, asked what was to be done for people who could not have radium or an operation. In his experience opium was far and away the best drug. He did not think it advisable to keep patients long in bed, they should be encouraged to go about their ordinary work. Professor HENDRY (Glasgow) had only very limited access to radium. Enlargement of glands was often due to simple septic absorption. Infiltration of glands often cleared up after the application of radium. Mr GILES had long been convinced that the importance of the glands was exaggerated. Recurrence did not appear in those glands, but low down in the pelvis about the site of the operation scar. Speaking of the relief of patients for whom operation and radium were not available, he favoured scraping away as much growth as possible applying chloride of zinc and filling up the vagina with a solution of sodium bicarbonate. This greatly diminished the irritating discharge. Dr FLETCHER SHAW (Manchester) found that his operation figures were practically the same as those of Mr Bonney. No one would operate if he could get as good results from radium but no one in England could produce figures to compare with Dr Gray Ward's with radium. Had they done right to leave radium in the hands of the radiologists? He thought

they ought to have kept the treatment in their own hands. He felt certain that they were going to get results in England, though they had not done so yet. He had been told by radiologists that radium was no good in cases of recurrence; they could see from Dr Gray Ward's results that this was quite wrong.

Dr GRAY WARD, replying, said that to-day he would not remove the uterus if the case was perfectly well after radiation. As to the glands, it had been demonstrated that the majority of enlarged glands were inflammatory, not carcinomatous. Theoretically high voltage x rays should block off lymphatic channels. Radium therapy in menorrhagia was the standard treatment in New York, the technique should ensure that the radium was in contact with the fundus uteri. Cuéttago should always be a preliminary. They used blood transfusion very frequently in cachectic patients. He urged systematic regular overhaul of every woman over 40.

Dr FARQUHAR MURRAY said that in regard to the standardization of case classification they were still in a state of chaos. Education of the public was necessary to establish an efficient follow up system. They must have more radium. He was profoundly dissatisfied with the results of operative treatment of cancer. Whether the place of surgery would be taken by radium it was yet too early to say. In regard to glandular involvement, he could not believe that, whoever operated, every gland could be removed. He thought that possibly minute deposits left behind might undergo spontaneous cure.

CEREBRAL STATES AND HEAD INJURIES

A discussion on the differential diagnosis and treatment of cerebral states consequent upon head injuries was opened by Dr C P SYMONDS, who said that, apart from the immediate surgical risks of compound fracture, the rupture of a meningeal artery, and subdural haematoma, the severity of an injury to the head varied with the nature and amount of damage suffered by the brain at the time of injury. Concussion was defined as a condition of subtotal cessation of cerebral function following immediately upon the injury, with subsequent complete recovery within twenty-four hours, at the end of which, in an uncomplicated case of concussion, recovery should be complete and permanent. The whole syndrome was probably due to temporary vascular embarrassment. Distinct from concussion, though often associated with it, was the condition of cerebral contusion. The symptoms of cerebral contusion depended upon two factors: (1) the effect upon intracranial pressure, and (2) the precise situation of the lesion. The focal signs of the latter were those of cerebral disease generally. For the purposes of clinical description, Dr Symonds distinguished between a major and a minor degree of contusion. The major form was almost always associated with concussion. After a few hours the patient partially regained his senses, but instead of making rapid progress towards a normal state he remained stuporose, restless, and irritable, and at night might be noisy, ballustrated, and violent. In minor contusion the injury might or might not have been such as to have caused concussion. It was possible for a glancing blow to bruise the brain without loss of consciousness at the moment of injury. The three most common symptoms were headache, giddiness, and mental disability. One of the most characteristic features of the headache was its relation to alterations of posture. The mental symptoms consisted of inability to concentrate, defective memory, loss of emotional control, and rapid fatigue of the mental processes. Apart from focal physical signs, which were rarely encountered, there were other symptoms, such as epilepsy and permanent mental change which must be related to focal damage. Lesser degrees of mental impairment, such as memory defects, were by no means uncommon, but permanent mental deterioration necessitating institutional care appeared to be rare. Epileptic attacks might occur even in the early stages of a major contusion and were probably due to subarachnoid haemorrhage. Of more serious significance were the attacks

which developed after a latent interval of months or years. Cerebral abscess following a compound fracture, and chronic subdural haematoma, although both rare, were two sequels of head injury which were likely to come within the view of the neurologist. Finally, there was a large group of cases in which the disability which followed head injury was wholly or partly neurotic, usually based upon the problem of compensation. It was important to remember that the brain might be scarcely damaged without fracture of the skull or objective physical signs, and that conversely, fracture of the skull was not in itself proof of cerebral damage. The signs of subdural haematoma were often those of cerebral tumour—papilloedema and hemiplegia. The cerebro-spinal fluid might exhibit xanthochromia and fibrin flakes. As regards treatment, complete rest was indicated in major contusion, and relief of intracranial pressure might be obtained during this stage either by lumbar puncture, if necessary, repeated at intervals of two days, or by an intravenous injection of 50 to 100 c.c. of 15 per cent hypertonic saline. An alternative method was to give a saturated solution of magnesium sulphate (3 oz. in 6 oz. of water) by the rectum, to be effective, this solution should be retained for half an hour. In a series of eighty patients with symptoms of cerebral contusion Dr Symonds found that eighteen, or 22.5 per cent, stated that they had made a complete recovery. In cases of major contusion the chances of the patient being able to return to full work were less than one in three, and there was the same chance of total incapacity. In cases of lesser injury there was an even chance of the patient being able to return to full work, and a very small risk of total incapacity.

Dr C WORSTER-DROUGHT emphatically agreed that the brain might be very seriously damaged without any fracture of the skull, or indeed evidence of bone injury. In assessing the effects and possible consequences of head injury far too much stress was laid upon the radiographic appearance of the skull, and, if negative, the cerebral injury was often assumed—not only in legal, but also in medical circles—to have been slight. In his experience the after-effects of what had been described as major contusion were more often severe than not, and personally he would not have placed the ratio of complete recovery in these cases so high as 22.5 per cent. One important point was that cerebral contusion might lead to localized adhesions between the dura, arachnoid, and cerebral cortex, and so give rise to epilepsy—all without x-ray evidence of bone damage. This was strikingly illustrated in one case that came under his observation—a case also noteworthy on account of the excellent result of surgical treatment. A man, aged 28, fell, striking his head on the junction of two tram lines. Three years after the accident his first epileptic fit occurred, there being no previous history of epilepsy. X-ray examination of the skull revealed no abnormality. When the region of the scar was trephined the dura was seen to be under tension, and on incision was found to be adherent to the underlying cortex. Dr Worster-Drought had had this patient under observation since the operation—six and a half years—and no fit whatever had occurred. The man had returned to work and was in excellent health. Equally successful was another case of traumatic epilepsy, due to a lesion that might be described as an unusual form of subdural haematoma in the posterior parietal region.

A prisoner of war aged 25 was struck on the head with the butt end of a rifle in February 1917. About a week later he had a fit there being no previous history of epilepsy. The fits occurred at intervals varying from one to eight weeks. A typical epileptic seizure was personally observed. Physical examination revealed no abnormality beyond a small scar in the right posterior parietal region. In March 1919 the region of the scar was trephined. Immediately on incising the dura there escaped about two drachms of yellow serous fluid and a saucer-like depression (which had apparently contained the fluid) was seen in the cerebral cortex. Dr Worster-Drought had had this case under observation since the operation—over nine years—and no further fits had occurred.

An interesting point, possibly, for discussion was, How long after a head injury could epilepsy appear? In his experience it had been common for epilepsy to appear three or four years after the accident, and he had met with cases in which the first epileptic attacks had occurred ten and

even twelve years after the head injury. As regards treatment of traumatic epilepsy, the conclusion was that in the presence of definite evidence of the site of injury, such as a scar, etc., even if radiographic appearances were negative and in the absence of other localizing physical signs, operation was worth while. He would not advise operation in the absence of physical signs or of some evidence indicating the site of injury. The mental sequelae of cerebral contusion were often peculiar. One somewhat unusual effect was complete and apparently permanent inability to perform mental work.

An undergraduate—head boy at his school and who obtained the senior classical scholarship at his university—had, following a head injury, become utterly unable to concentrate or settle down to serious study, and he retained nothing he read. Entering on his university career with all promise of a brilliant future, he was compelled to come down without a degree, having entirely failed in his final examinations. It was now five years since the accident and he showed no signs of improving in respect of his particular disability.

Dr Worster-Drought considered that head injuries in the alto frontal region were the most serious as regards prognosis in respect of mental changes. A condition of dementia might result from damage in this situation. In view of the fact that W. E. Dandy in America had recently excised the right cerebral hemisphere without (it was reported) the patient showing evidence of mental change, such injuries to the left frontal region were of interest in localizing the main seat of intellectual activity. Another point for discussion was how far a severe head injury might light up a latent psychosis. As regards treatment, Dr Worster-Drought was not convinced of the practical value of intravenous injection of hypertonic saline, the relief of symptoms afforded was somewhat uncertain and transient. He mentioned experiments supporting this contention. He was inclined to regard lumbar puncture, repeated if necessary, as the best means of relieving intracranial pressure. The continued administration of saline substances, either by the mouth or rectum, might, however, also be of value. For chronic and persistent headache following head injury, when repeated lumbar puncture failed to give permanent relief, Dr Worster-Drought was in favour of subtemporal decompression. He had seen several cases in which this operation had given excellent results.

Dr I. S. WILE (New York) remarked that in children cerebral contusion might lead to changes in personality, accompanied by delinquency and epileptic equivalents, resembling the sequelae of epidemic encephalitis. It was necessary carefully to distinguish the headache, giddiness, and various mental disabilities following minor contusion from psychoneurotic symptoms. Also, all the mental disabilities of attention and memory might be purely affective symptoms. It was important to employ psychological tests in determining defects of memory, whether visual or auditory, for recent or remote events. The relation of cerebral injuries to later educational disabilities could only be determined by more thorough psychological investigation. In his opinion caution should be exercised in prognosis regarding epileptic seizures after head injury. At least three years should pass before reasonable certainty that seizures would not occur, such seizures did occur even at longer intervals. Traumatic neuroses might be exaggerated in frequency, but it was wise to be certain that minor mental symptoms were not functional before suggesting that they were the residua of organic disease or cerebral injury. He agreed that emphasis was necessary upon the statement that fracture of the skull was not proof of cerebral damage, and that, conversely, damage of the brain might exist without a fracture of the skull. In order to interpret the actual state of a patient following cerebral injury it was necessary to know if he returned to his earlier occupation, or was subject to further re-education, or was obliged to change by reason of changing industrial conditions.

Dr R. D. GILLESPIE said that the classical psychotic syndromes had no specific etiological relationship to trauma. Certifiable insanity was very rarely the result of head injury. Of 71,000 admissions quoted by May, only 0.3 per cent could be called traumatic psychoses. In some cases that had been recorded other factors had been prominent,

such as intemperance, alcoholism, etc. Several groups of late after-effects could be distinguished, including traumatic defect states—general or local, temporary or permanent, including traumatic, mental enfeeblement, behaviour disorders, psychoneurotic states, and malingering. The chief difficulty arose in the diagnosis of these defect states from those of psychoneurosis, nevertheless, definite criteria existed, such as slowing of thought, attention defect, and mood disorders, also the patient should invariably be considered as a whole, especially his previous personality.

Mr WILFRED TROTTER said that until recent years a whole train of symptoms following head injury had been regarded as vaguely due to hysteria, malingering, etc., but that such symptoms had been brought into the realm of scientific observation, and were no longer vague and indefinable. It was possible to distinguish as precisely as anything in medicine a form of amnesia that was characteristic of true concussion. This was retrograde amnesia—a loss of memory for events preceding the accident, the patient having no recollection for anything that occurred during the fifteen to twenty minutes that preceded his head injury. A further point of diagnostic importance was that in the headache following minor contusion the patient, when free from headache, felt perfectly well. This was not the case with the psychoneurotic. As regards surgical treatment, this was called for in the conditions already mentioned—namely, compound fracture and meningeal haemorrhage. For intractable headache following minor contusion a decompression operation was indicated. In major contusion Mr Trotter doubted if it was justifiable to leave the brain in a seriously congested condition for a long period. He advocated the special operation of making a small opening in the skull to interrupt the vicious circle of compression.

Dr D. McALPINE confined his remarks to the question of treatment. Only of late years had increased intracranial tension been recognized as the important factor in cases of head injury. This rise of pressure was brought about by traumatic oedema or haemorrhage, or by a combination of both. Oedema resulted in a general enlargement in the size of the brain, which tended to bring its surface close up against the dura. The effect of this was to hinder in varying degrees the absorption of the cerebro-spinal fluid into the venous sinuses. But as the fluid continued to flow from the choroid plexuses and accumulated in the ventricles and basal cisternae, more and more pressure was brought to bear on the medulla until it became paralysed. In some cases, therefore, traumatic oedema resulted in death from medullary compression, and this was a fact that could not be overlooked from the point of view of treatment. Lumbar puncture afforded an easy means of reducing the tension, and was practically free from danger in cases of head injury, except in the stage of shock. As long ago as 1905 Quincke pointed out that in brain injuries the estimation of the cerebro-spinal fluid pressure was of importance, and that the best results were obtained by drainage. Little importance had been paid until recently to the principles underlying this observation. A rise in the blood pressure accompanying intracranial tensions was true only of the late stages of medullary compression, and it should not be relied upon as an early sign. The only sure guide to the tension of the cerebro-spinal fluid was the manometer. The normal reading of the spinal fluid pressure in millimetres of mercury lay between 6 and 8. The patient should be in the prone position with the head, spinal canal, and upper level of the meningeal columns in approximately the same horizontal line. When the stage of shock following a head injury has passed and no immediate surgical interference was called for, lumbar puncture should be performed and the tension of the fluid measured. If this was raised sufficient fluid should be allowed to drain away to reduce the tension to just below normal. Lumbar puncture should be repeated at the end of twelve hours in a case of any severity and so on daily until the tension returned to normal. If after two or three punctures it was found that the tension was increasing, then the advisability of cerebral decompression should be considered.

Dr G. RIDDIOCH said that it was important to separate anxiety states from those of post-traumatic defect. The

latter were of the order of a mild dementia—deterioration of general mental capacity. The patient's symptoms tended to become worse towards the end of the day, whereas in anxiety states the symptoms were usually most pronounced in the morning. The symptoms were mainly those of lack in mental and physical efficiency, and were an indication of the effect on the brain as a whole rather than a sign of local contusion. Mr Trotter had suggested the term "post-contusional submentation" to indicate this condition. Dr Riddoch considered that hypertonic saline, given preferably by the rectum, was of value in relieving intracranial tension, but that the method should be used with discrimination. Dr E MAPOTHER expressed surprise that various speakers whose experience of head injury must be larger than his own should have found acute and severe psychoses so rare as a sequel of head injury. He referred to three such cases directly following severe motor car accidents. In all of these cases the salient feature was a manic state, a joyous satisfaction with self and circumstances, and disjointed hyperactivity. This was associated in a manner that was not seen in an ordinary mania with confusion. Disorientation and amnesia for current events was also present, in fact, all three cases resembled a combination of mania with Korsakoff's syndrome. All three cases had followed prolonged unconsciousness after the accident, and in one cerebro-spinal fluid escaped from the ear for a week. The patients all recovered within a few months. The condition observed was certainly not of purely emotional origin, and the patients had never shown previously a neurotic or psychopathic disposition. Dr PICKWORTH (Birmingham) said that the connecting link between head injury and mental disease was vascular, and was found in local or general cerebral anoxaemia or the results consequent upon inadequate removal of metabolic waste products. There was a remarkable similarity in some of the mental symptoms, which might occur in chronic subdural haemorrhage, simple anoxaemia, and anoxaemia produced by carbon monoxide poisoning. Almost any symptoms of mental disorder might be reproduced by this condition. Chronic subdural haemorrhage or history of head injury was not rare in mental hospitals.

Mr GEOFFREY JEFFERSON (Manchester) added his testimony to the importance of the condition of retrograde amnesia which Mr Wilfred Trotter had mentioned. This observation was of the utmost importance, for one had to correlate the patient's present complaint and condition with the amount of injury which he had received. Another point was the anatomical basis of these contusional states, be they recent or remote. Histological study on fatal cases showed a widespread minute change. He believed that changes of a similar or lesser degree existed in those patients who finally recovered. The outstanding feature of the finer changes in the brain tissue was cerebral oedema, so that the perivascular sheaths were distended or ruptured. The question of treatment must be based largely on pathological anatomy and its physiological results. If gross haemorrhage was present the treatment was obvious. It was the oedematous cases which presented the difficulty. Mr Trotter had performed a service in voicing his doubts as to whether they were right in allowing patients to be for long in a condition of restless unconsciousness, and there could be no question that judicious surgery held a place in treatment. If it was certain that the brain was oedematous hypertonic solutions (and 50 per cent glucose rather than saline was preferable) should succeed, but if a temporary improvement was followed by relapse decompression was necessary. Dr R EAGER (Exeter) had had the opportunity of studying during the war a series of 100 cases of head injury in which the patients had developed more or less mental symptoms. Headache, usually severe, was constant, and often varied with the position of the head. In some cases the patients sought refuge from the headache in alcohol, or even attempted suicide. This alcoholic refuge had not been sufficiently realized, and had in some measure been misinterpreted. Other symptoms included restlessness, lack of self-confidence, irritability, lack of concentration, and in some cases hallucinations. Epilepsy occurred four times more frequently in severe injuries than in milder cases. The injuries in those cases in which memory defect was a conspicuous feature were mainly in the frontal region.

Dr Eager had found a relatively small proportion of cases in which mental symptoms were the direct result of head injury.

THE EARLY TREATMENT OF THE PSYCHOSES AND PSYCHONEUROSES

Dr HELEN BOYLE (Hove), opening a discussion on this subject, divided it into the early treatment of the individual, and how this could best be obtained. Insanity, she said, began before a person was insane. Although the early detection and treatment of mental defectives would not lead to cure, it would in many cases protect the community by helping to make the patients partly self-supporting and less dependent, segregation would avoid the possibility of mentally defective children being born. Many, if not most, of the difficulties found in education, criminology, religion, industry, and general medicine could only be solved with the aid of mental medicine and an understanding of the mind of man in health and disease. No doctor would admit that an understanding of the body in health was foreign to his purpose of grappling with disease. No doctor should any longer admit that an understanding of the mind in health was redundant, and still less of the mind diseased. The intricacies of its connexion with the body still needed further elucidation. The early treatment of recent cases in mental hospitals had improved immensely in recent years. The hospitalization of asylums was progressing, but Dr Boyle wished to dwell, not on the certifiably insane treated in mental hospitals, but on the patients whom it was harmful to certify or who were uncertifiable, the large number of the maladjusted, and those labouring under obsessions, phobias, and inhibitions. For these cases early treatment was necessary to prevent faulty adjustments. Dr Carswell started wards for borderland patients in connexion with the Poor Law, and the Lady Chichester Hospital, Hove, the first hospital for these cases, was started in 1905. Dr Rayner, about 1889, induced the governors of St Thomas's Hospital to open an outpatient department for early mental cases, since then many others had followed suit, notably Cardiff, under the President of the Section. The Maudsley Hospital was started in 1923 after previous use as a war hospital, it was carried on under special conditions, and was a centre for training and research of immense value, supported by the London County Council. The Cassel Hospital was providing for those who could afford moderate fees. For children who showed maladjustments in school life or before, the child guidance clinics offered useful help. Two were already in existence in England, and an elaborate one in London was being planned with American help. Dr Boyle suggested that it was desirable (1) that every general hospital should have facilities for treating early nervous and borderland patients, (2) that child guidance clinics should be available for the young maladjusted children and be under the charge of doctors, (3) that delinquents should have expert examination with regard to their mental adjustment—on the first offence—repeated if necessary, (4) that voluntary boarders be allowed in county mental hospitals, (5) that early insane patients should be able to be treated on two doctors' certificates, (6) that vocational guidance should be available for all who wish it—as at the National Institute for Industrial Psychology—as a preventive measure against maladjustments and unrest, (7) that every medical student should be obliged to devote some time to the study of all forms of mental disorder, (8) that examining boards should require evidence of knowledge of all forms of mental disorder.

Professor W WYGANDT (Hamburg) said that one of the chief difficulties was the recognition of pre-symptomatic cases, such as in Huntington's chorea, which was hereditary, but only in the fortieth year or later did symptoms appear. In the commoner types of mental disorders there was an inherited predisposition—for example, schizophrenia, cyclothymia—and even in early youth latent symptoms might exist. These it might become possible to discover by biological and psychological methods. There had already been several attempts to investigate children liable to mental disorder, such as those of Bechterew at Leningrad and Rossolimo at Moscow. At Hamburg there was a clinic for the observation and treatment of psychopathological boys by specially trained medical men and teachers.

Dr I S WILF (New York) said that the prevention of psychoses and psychoneuroses to be adequate should be undertaken in childhood. From the experience at his own clinic at the Sinai Hospital, New York, he considered that a large part of the work could be carried on in the out-patient department. The type of problem met with could be classified under three headings: (1) social mal-adjustments, (2) inadequate and undesirable habit formations, such as insomnia, night terrors, difficulties with food (fads), and speaking, (3) personality trends—as, for example, timidity, selfishness, unpopularity, and seclusiveness. The precocious child was often a more difficult problem than the defective. The mode of treatment depended upon interpretation of possible factors at work: this involved a diversification of procedures, dependent upon whether the dominant element lay in the physical, intellectual, emotional, or social realm. Life was manipulated as a whole rather than as a part because, by the very nature of man, to affect one part was to affect all. The time had passed for differentiating physical and mental factors as mutually exclusive.

Dr L MIRONEN agreed that in smaller country towns an out-patient department or a couple of wards might be all that was attainable, but not that such arrangements were the ideal at which to aim. He made no pretence of freedom from bias in advocating the psychiatric clinic, wherever possible, as against Dr Boyle's policy of a ward or department in a general hospital. He insisted that (1) it was wise not to rationalize into laws of nature restrictions and separations and vested interests which had really grown up from the absurdities of the Lunacy Act of 1880 and from the popular phrase, "It is not mental, doctor, it is only his nerves"; (2) the whole trend of every progressive country in Europe after twenty years' experience was towards establishment of special clinics; (3) detailed knowledge of attempts in Great Britain to establish psychiatric treatment in general hospital wards was the best evidence of their inadequacy. The usual general hospital scheme—visiting honorary physician, juvenile and inexperienced house-physicians, and nurses working in wards of a special kind just for a few months during training—was quite inapplicable except to a most limited class of neurotic patients. The proper ideal was a special building designed for the reception of patients with every degree of mental disorder and for their proper classification, with a highly trained semi-permanent staff and full provision not only for all forms of treatment, but also for occupation, exercise, and amusement during months of stay.

Dr MARI BARKAS said that it was too often assumed that early and recoverable cases were necessarily mild ones not needing the resources of a mental hospital for their treatment: this was far from being the case for it was just those eminently recoverable acute patients who broke down rather suddenly without such prodromal signs as were likely to be noticed, and who formed the group in which prognosis was best, while those of more insidious onset were, unfortunately, quite often the most intractable. Thus there was a danger in stressing too much the hope that by providing facilities for early treatment a rapid decrease would be ensured in the burden laid by insanity on the community. In certain American States it was averred that the opening of clinics and psychopathic hospitals had materially reduced the numbers requiring asylum care, but to make the proof of such a reduction within a short period a criterion for the value of the provisions for early treatment might well result in a feeling of disappointment that no such effects were demonstrable. An extension to all patients of the provisions now available for private patients with adequate supervision by the Board of Control—a thing no general hospital was likely to welcome—would do much to supply all that was needed for the present. In this connexion the present voluntary boarder system would probably before long be made to apply to all patients, but unless this was altered to conform more to the lines of provision now made for alcoholics, Dr Barkas did not think that it would do much to solve the problem. Child guidance clinics had shown how greatly the problem of the psychopathic child was bound up with social considerations, and

how all-important was the social worker and the re-education of the family. With the adult neurotic the same held good, and the speaker believed that no clinic for either in- or out-patient treatment would be able to do satisfactory work unless it included a well-trained staff of social workers who could deal with the environment of the patient.

Dr R G GORDON (Bath) considered that there was a good deal of confusion of thought on such questions as the following: Was there any fundamental difference between the neurotic and the psychotic patient? Did the neurotic patient ever become insane? Did the neurotic or normal person ever commit suicide? What was the real meaning of the borderline case? To answer these questions there must be an intensive study of the personalities of individuals, whether sound or sick, and particular attention to the capacity and success enjoyed by these persons in their adjustments to their environment. If this was done Dr Gordon suggested that it would be found that the person who under certain conditions—whether of toxæmia, endocrine disturbance, mental conflict, or emotional shock—broke down into a psychosis, differed in his "personality make-up" from another patient who under similar conditions broke down into a neurosis. Moreover, one of the chief differences seemed to be that in the first case the personality had no real tendency to adjust to the environment, and that in the present state of knowledge the efforts made did not at all, or only to a slight extent, increase this adjustment to the environment. With gently increased knowledge it might be possible to foresee that in certain circumstances which might be avoided "A" would break down into a psychosis of a particular kind, say manic-depressive insanity, "B" into a psychosis such as dementia præcox, while "X" would break down into a neurosis of a certain kind, say an anxiety state, while "Y" would develop hysteria. This was an ideal situation, and at present probably no one pretended to be able to carry out such subtleties in diagnosis, yet increasing experience seemed to be pointing that way.

Dr J R REES said that comparatively few realized that the moral disorders, the character and personality defects of childhood, were the forerunners of much of the mental disorder of later life. The statistics of the Tavistock Square Clinic bore out Dr Boyle's figures in showing that medical practitioners were gradually waking up. An increasing number of children and adults were coming on the recommendation of their doctors but there was still a great deal to be done. In medical as in lay minds there was still a gulf fixed between physical disorders and mental trouble. There was "real" disease and "imaginary" disease, and hence arose so much hopelessness, visionless, and empirical treatment of the mental disorders. Psychology was the nursery or the infant school, and the general practitioner was the ideal person to tackle this early period. He had the entrée to homes and the confidence of patients. The people and also the profession must be educated. He suggested that the British Medical Association might initiate a campaign of education. The mental hygiene movement in America did a vast and admirable work which was practically left untouched in this country. Was it not possible that there should be short courses of lectures for practitioners in every Division? The general practitioner, with his experience and balance, was well able to grasp the essential facts that were known, and he would in consequence be better equipped to deal with the earliest manifestations of mental trouble and to perform preventive work of inestimable value. Clinics, early treatment centres, and child guidance centres must come, and it seemed to him essential that the profession should have adequate knowledge if it were to co-operate effectively with these specialized institutions.

The President, Dr L GOOBYLL, said the delay in dealing with the recommendations of the Royal Commission on Mental Disorders in respect of facilities for early treatment was deplorable. He detailed the arrangements at Cardiff for dealing with early cases in an out-patient department of the Cardiff Royal Infirmary during the past seven or eight years. In his opinion 60 to 70 per cent of the out-patients required indoor treatment. In

the plans of a large new hospital, now being erected by the Poor Law authority at Cardiff, was included a wing for neurological cases and a pavilion for psychiatric cases, but this was a development for the future. Dr Goodall stated that the 30 to 40 per cent of patients among the direct admissions to the Cardiff Mental Hospital who were annually discharged within six months of admission could be treated at a psychiatric clinic, quite apart from the lunacy laws as at present constituted, and all the drawbacks which those laws implied. His constant advice to the Cardiff local authority was to abstain rigidly from any addition to their mental hospital, and to concentrate upon provision, in conjunction with the Cardiff Infirmary, of a fully equipped clinic in psychiatry.

Dr DONIS OULUX (Bournemouth) said that the discussion had shown a few points of difference of opinion, but more of agreement. All agreed as to the need for early treatment, all appeared to agree as to the value of establishing out-patient departments in association with general hospitals. She emphasized this not only in the interests of the patients, but also as a means of educating the public, the nurses, and the doctors in other departments of the hospital. The association with the general hospital gave status to the whole subject. All agreed that in-patient accommodation was essential. Everyone was strongly in favour of adequate social service in association with the out- or in-patient clinic, specially trained welfare workers were essential. The suggestion for the establishment of small hostels for patients who came from a distance for out-patient treatment in a centre was quite uncontroversial, and also the idea of starting special convalescent homes for recovering cases. Dr W. A. POTTS (Birmingham) said that no one yet had mentioned the two most important places for early treatment to be carried out. Those centres were the infant welfare clinic, which provided the earliest opportunity for the examination and training of the child, and the ante-natal clinic, where the attitude of the mother, and also of the father, to life and also to the child might be investigated and corrected. It was necessary to correct any misunderstanding that might arise from what was said about the damage of a sentimental attitude towards delinquents by saying that those who were engaged in work with delinquents were out for justice and for an opportunity for developing and drawing out the diminished sense of responsibility many delinquents had. The time would come, if early treatment was adopted, when very few wards would be wanted. Among the patients who came to Dr Potts for treatment the most hopeful were those who came saying they could not leave their work, such patients nearly always did well. Dr R. S. ALLISON (Ruthin) referred to some physical aspects of the treatment of the psychoneuroses. The first essential after obtaining a careful history was to make a thorough physical examination, following this, investigations would suggest themselves along bacteriological, biochemical, and radiological lines. The object in making these investigations was twofold: (1) the search for toxic foci, (2) to ascertain the physical peculiarities of the patient. The teeth, the throat, the accessory sinuses of the nose, the appendix, the gall-bladder, the colon, and the urine and faeces were commonly the sites of a latent infection. In some cases this might be detected only after a full investigation. Dr C. FORBES (Aberdeen), speaking as a general practitioner, supported strongly Dr Rees's suggestion regarding the education of the medical profession. The proposition should be urged by all who were interested in the general practitioner and in the early treatment of mental and nervous illness. There was a definite need for the institution of clinics as a medium not only of research and treatment, but also for the education of family doctors in the particular area served. The great majority of general practitioners were interested and acutely concerned in the problem under discussion. Dr CONSTANCE MORTLOCK-BROWN (Braunton, Devon) said that her objections to the Provisional Treatment Order were that it increased the number of orders instead of reducing them, it did not protect the patient and relatives from stigma, since sojourn in an asylum was a greater stigma than certification, she objected to two doctors interviewing the patient together, the Provisional Order did not secure for the patient and his relatives the rights and privileges, such as they were,

which were now accorded them under the 1890 Lunacy Act and attendant rules, under the Provisional Order a patient would be condemned to asylum life definitely for six months or a year—a most depressing outlook—whereas he might recover in three months or less. There was no necessity for a visit from a magistrate to be made obligatory, but it was advisable for him to have the power to visit. Dr Mottlock-Brown further urged that the terms "lunacy" and "lunatic" should be expunged from the statutes and from medical writings and conversation, and that medical women should be appointed to the Board of Control. She wished particularly to thank the British Medical Association that it had supported the rights of medical women in this matter. The Royal Commission, however, had suggested their appointment to a subsidiary position under a laywoman.

SECTION OF DERMATOLOGY

Friday, July 27th

URTICARIA

SIR ROBERT BOLAM, President of the Section, took the chair, and called upon Dr A. R. HALLAM to open the discussion on urticaria.

Dr HALLAM (Sheffield) said that urticaria, more than any other disease, exemplified the close connexion between cutaneous and general medicine. He defined four groups: (1) factitious urticaria, (2) acute urticaria, (3) chronic urticaria, and (4) the papular urticaria of childhood. According to Lewis, in all cases the wheals were due to the liberation of a histamine-like substance in the skin. The papular urticaria of childhood, although closely related to the urticaria of adults, differed in that the characteristic papule, instead of disappearing within a few hours, persisted for about a week. A remarkable fact, first noted by the speaker, was that all patients admitted to hospital immediately got well without the aid of any active treatment, but relapsed on discharge. According to Lewis wheal formation could be accurately imitated by an injection of histamine. The phenomenon of undue sensibility or allergy in urticarial subjects had been established, but the nature of this condition had not been discovered. The resemblance, however, between urticaria and anaphylaxis, first advanced by Wolff-Eisner, had been thought to show a close connexion between the two conditions, in both of which there was a fall of blood pressure, leucopenia, moderate eosinophilia, and sometimes albuminuria. The causes of urticaria were most varied, among them there had been recorded the passage of a uterine sound and a ring at the front door, it might be one of the earliest signs of grave disease or might be associated with focal sepsis. Since the chance of successful treatment largely depended on the detection of the cause, each case must be considered minutely from all aspects. Should the offending antigen be detected desensitization might be attempted, but empirical remedies often had to be employed. Calcium salts had long been used, but had not often been successful in the speaker's practice. Thyroid extract was sometimes beneficial.

Dr H. W. BARBER read a paper by himself and Dr Oriel on the biochemistry of the allergic state, of which urticaria was one of the commonest manifestations. Allergic conditions, he said, included (1) cutaneous reactions, such as in urticaria, various forms of eczema, and other dermatoses, and angioneurotic oedema, (2) respiratory reactions—as, for example, hay fever and asthma, (3) gastro-intestinal, and (4) nervous reactions, including migraine and possibly other conditions. Dr Oriel had discovered a phenomenon in the urine, termed the "other" reaction, this was always strongly positive during an acute manifestation, but might disappear during the period of quiescence. The two authors had found that in normal subjects the amino-acid content of the blood varied between 4 and 6.5 mg per 100 c.c.m., but in many allergic cases—as, for example, the asthma-prurigo group—very high quantities were found during the acute stages. Raised amino-acid content had also been found in light sensitization, in dermatitis herpetiformis and other cutaneous conditions, and in some cases of cirrhosis of the liver. They had found that chlorides tended to be retained in the blood during the paroxysm,

but excreted in unusually large quantities subsequently, urates were commonly deposited in the urine during the pre-oxysmal phase. It appeared that this precipitation depended on the urinary colloids, not, as previously thought, on the concentration and acidity of the urine. A urine with low acidity and a specific gravity of only 1012 might give a copious precipitation of urates. The ammonia excretion was very high during acute attacks, and was out of all proportion to the acidity of the urine. During the post-oxysmal stage there was diminished acidity, and sometimes actual alkalinity with diuresis. The speaker thought that the deposition of urates and the ether reaction in the urine indicated an alteration in its colloidal state, and that the increased ammonia excretion with the retention of chlorides in the blood were protective mechanisms. In general, they had formed the conclusion that the allergic state was associated with hepatic insufficiency.

Dr H G SEMON inquired (1) If hepatic insufficiency was the cause of allergy why did not urticarial symptoms occur in examples of gross liver disease such as arsenical poisoning? (2) In what other diseases were amino-acids increased in the blood? He had found ephedrine useful sometimes, and the intravenous injection of calcium effective in other cases, especially in angioneurotic oedema. Dr W J O'DONOVAN said that allergy as defined by Dr Bailey was too comprehensive, in ascribing it to liver torpor he was going back to Sidenham. He agreed that there was a neurotic factor. Dr J BEATTY (Cardiff) said that hepatic insufficiency was too extensive a cause for so narrow a group of diseases as urticaria and its allied conditions. He doubted whether the nervous system could excite urticaria. He himself regarded urticaria as a reaction of the skin to general protoplasmic poisoning. Dr HILL (Leicester) suggested that chronic infection with *Bacillus coli* was a common cause of urticaria.

Dr BARNES, in reply, said that he and Dr Oriel did not claim to have discovered the cause of urticaria, they had merely described the biochemistry of the allergic state. In answer to Dr Semon he said that allergic symptoms, such as itching were present in liver disease. He had found that calcium was useful when there was calcium deficiency affecting the vegetative nervous system, which varied in irritability according to the calcium content of the blood. He was aware of the utility of ephedrine and adrenaline. Dr HALLAM, in reply, said that as yet there was no specific for urticaria, the only thing to do was to try to find the actual cause. Otherwise empirical remedies, countless in number, were the sole hope.

SOUTAR'S STEAM CAUTERY IN DERMATOLOGY

Dr H G SEMON read a paper on the dermatological indications for Soutar's steam cautery which he had used for over two years, and much preferred to diathermy. Its advantages were freedom from breakdown, slow penetration of the tissues, it was easily regulated, and the production of a coagulum which although firm, could be easily removed with a sharp spoon. The source of heat was a solid fuel, the apparatus was therefore portable and quite independent of a lighting circuit, but owing to the presence of a naked flame proximity to ether must be avoided. Mechanical trouble was extremely rare with this instrument. The most important precaution was to keep the applicators free from crusts, which reduced the efficiency. Another advantage was the ease with which haemorrhage was arrested, even if large arteries were opened again, there was a striking and complete absence of post-operative pain. He had found the cautery particularly useful in epitheliomata invading cartilage or bone—cases in which x rays or radium were well known to be almost futile. He had also used it with great success in three cases of lupus verrucosus, but the horny tissues must previously be macerated with strong salicylic plasters for a few days, because the applicators had no effect whatever if this were not done, such was the heat-resisting power of keratin. He also used it in treating soft sores and chancrelets, for the bacillus of Dnerev was notoriously susceptible to the effects of heat. The type of case in which his experience led him to expect the best results was one in which the pathological tissue to be destroyed was soft in character and free from keratin, warts, fibro-

mata, and moles should be avoided. The after-treatment consisted in keeping the part as dry as possible until the slough separated, when ambrino was the best dressing.

Dr WIGLEY, in the discussion, suggested that it would be convenient to employ an electrical method of heating the water. Dr SEMON, in reply, said that there was a difficulty in obtaining an electric heater appropriate for the many different electrical circuits in operation.

THALLIUM EPILATION IN RINGWORM

Dr J E M WIGLEY read a paper on the treatment of ringworm of the scalp by thallium acetate. He said that he had treated fifty cases in children varying in age from 18 months to 9 years. The dose had been 85 mg. per kilo of body weight, dissolved in an ounce of sweetened water. He had found the average time of epilation to be twenty-four to twenty-six days, and recommencement of growth much more rapid than with x rays. He had checked all his cases by examination with ultra-violet light under Wood's glass. He had found that many unbroken hairs apparently normal in appearance were merminated by the ultra-violet method, and these were always found microscopically to be full of mycelium. Thallium often gave a deceptive appearance of cure, but failed to pass the Wood's glass test. The local treatment so strongly insisted upon by several writers during the period of hair falling was very difficult for out-patients. Toxic symptoms were noticed with the greater frequency the older the patient, pain in the legs was the commonest. He had tried thallium in chronic seborrhoeic dermatitis of the scalp without success. He concluded that thallium was distinctly inferior to x rays in the hands of a skilled operator.

Dr HALDIN-DAVIS thought that the scope for thallium was limited to children who were too young for x ray treatment, but with the aid of a narcotic it was possible to x ray quite young infants. He, too, had noticed the occurrence of hairs heavily infected with ringworm but appearing quite normal to the naked eye. Dr SEMON said that he had used thallium in over forty cases with only one failure. It entailed much more work by the dermatologist and his assistants than did x rays but was much safer unless the x rays were given by a skilled and experienced person. Dr O'DONOVAN had given up thallium and thought it should be limited to Poor Law institutions where x rays were not available. Dr HALLAM reported that he had treated eighty-two cases with thallium, and considered it safer than x rays, forty of these patients were kept in bed during the period of epilation. He had had only one failure. Among out-patients his results were not so good. Both x rays and thallium were bad methods. Dr INGRAM (Leeds) said he had treated forty-eight cases successfully, he had also found it useful in chronic seborrhoeic dermatitis of the scalp. The PRESIDENT reminded the Section that Sir Norman Walker had recommended them to experiment with these methods on favus in which one was justified in taking more risks than in ringworm. He had done so, and he agreed with Dr Hallam that both methods were bad, he still kept an open mind as to their relative merits. Dr WIGLEY in reply, said that he was more against thallium than against x rays on account of its uncertainty.

SALVARSAN ILL EFFECTS AND FATALITIES

Dr W J O'DONOVAN, in a paper on uncommon ill effects of salvarsan therapy, said that it was impossible to predict what patient would prove unsuitable for salvarsan treatment. Ill effects might occur at any time during the course, with any brand of drug, and with any sized dose. He mentioned certain cases which were interesting because of their gravity and comparative rarity. They included post-salvarsan melanoderma, one case being associated with follicular hyperkeratosis, multiple cutaneous abscesses with exfoliative dermatitis, cutaneous and subcutaneous necroses and pulmonary embolism. He had shown two cases of melanoderma at the Royal Society of Medicine, and although doubt had at one time been thrown on their etiology, his conclusions had since been accepted. The patient, who had suffered from cutaneous necrosis, also had necrosis of the bone of

the os calcis, this had never before been described as a result of salvarsan. This patient recovered, but the patient who had pulmonary embolism succumbed. The PRESIDENT said that he thought cutaneous accidents were more likely to occur when too frequent doses were given, and that hepatic troubles were due to excessive quantities administered.

SECTION OF LARYNGOLOGY AND OTOTOLOGY

Thursday, July 26th

DRAINAGE OF BRAIN ABSCESS

SIR PERCY SARGENT, who read the opening paper of a discussion on the drainage of brain abscess, remarked that it was essential to remember that some cerebral tissue required most careful surgical handling on account of its functional importance, though it had been demonstrated that practically complete destruction of one-half of the cerebellum had resulted in no apparent loss of function one year later. There were four types of brain suppuration with abscess formation: (1) diffuse suppurative softening; (2) formation of a septic cavity containing pus, with softened wall, but with no capsule; (3) a cavity lined with a thin capsule of young fibrous granulation tissue; (4) a small abscess cavity, surrounded by dense fibrous tissue of varying thickness. He discussed the nature and treatment of these types. He then showed a very interesting picture demonstrating the susceptibility of the lateral ventricle to involvement in cases of cerebral abscess, and emphasized the difference between a hernia cerebri and a fungus cerebri. Embolic brain abscesses were quite a favourable type for treatment. In these the transarachnoid route must be undertaken as near the abscess as possible, while in otitic abscesses the stalk should be followed.

Mr SYDNEY SCOTT concentrated on the treatment of brain abscess of otitic origin. Cerebral abscesses could be reached (1) through the roof of the antrum by the tegmen route, (2) by the labyrinthine route, if clinical signs of a dead labyrinth were present or there was evidence that the labyrinth had been dead for some years, or (3) by following the infection along the sinus route in the case of temporo-occipital or even occipital abscesses. Cerebellar abscesses might be opened (1) through the posterior wall of the antrum mesial or lateral to the sigmoid sinuses, (2) through the sinus, or (3) through the labyrinth (again if dead). For opening the skull he always used a gouge and hammer, he mentioned several cases in which he had proved to his own satisfaction that the blows of the hammer did not induce any headache or concussion, but he admitted that the circular trephine was the more popular instrument. He gave the warning that abscesses might be much deeper than was expected from their external appearance. He raised the question whether it was advisable to evacuate the pus rapidly or by suction and thought that perhaps slow drainage was more satisfactory. As regards the frequency of brain abscesses, it was found that only 85 cases had been admitted to St Bartholomew's Hospital in the last twenty-four years, and about the same number had been admitted to the Edinburgh Royal Infirmary in the last twenty years. In St Bartholomew's Hospital there had been 17 recoveries out of the 85 cases, and this proportion was found to more or less agree with the results at other centres in America and Vienna. In Neuman's clinic there had been 82 cases of temporo-sphenoidal abscess, with 20 recoveries, in eighteen years. He mentioned a record of 41 consecutive cases of cerebellar abscess, all of which were fatal. He commented on the curious fact that often the patients with the most severe symptoms were the ones who recovered following drainage.

Mr E D D DAVIS did not believe much in the efficacy of drainage tubes in dealing with brain abscess, and showed two drawings illustrating their failure to enter or remain in the cavity. Drainage tubes might give rise to secondary infection. Mr WAGGETT emphasized that the most important point was the detection of the abscess, and said that he considered the finger was the most useful in this. Sir Victor Horsley had been a convert to this method of exploration which he latterly made use of. Dr WILLIAM

HILL asked why frontal lobe abscesses were so much more serious than others. Dr HUGH JONES thought that the great obstacle to drainage was oedema of the brain tissue and distension of the ventricles, and suggested that possibly drainage of the ventricle through uninfected brain tissue might be of service. He thought that a double rubber tube afforded the best drainage, and also that the suction method might cause breaking of the wall of the ventricle. Mr RIDOUT (Portsmouth) said that experience tended to show that the more rapid and earlier treatment of infective otitic conditions had brought about a reduction in the number of cases of intracranial complications. He had treated 15 cases in about the same number of years, and in his personal experience cerebellar abscesses had done better than cerebral abscesses. Mr RITCHIE RODGER raised the question whether it might not be better to wait for brain abscesses to become encapsulated before operating, but did not offer it as a line of treatment to be adopted. He was inclined to this idea by the success attending operations on well-developed and encapsulated abscesses. Dr COATES (Philadelphia) said that the ideas, results, and frequency of this condition as detailed coincided pretty closely with those in the United States. Dr SYME (Glasgow) was interested in what Sir Percy Sargent had said about lumbar puncture. He was opposed to this procedure, but now that he had been told that the pressure was from the ventricle to the abscess, and not vice versa, he thought that it was justified. He doubted the value of packing gauze round the bone margin before opening and draining the abscess. Dr LOGAN TURNER (Edinburgh) asked Sir Percy Sargent if he had any experience of the gauze method of drainage as practised by Professor Fraser of Edinburgh, instead of drainage by tubes.

SIR PERCY SARGENT, replying, stated that intracranial pressure could be reduced in any given case temporarily by the intravenous administration of a 30 per cent solution of sodium chloride or by the introduction into the rectum of a saturated solution of magnesium sulphate. The danger was that the brain might fall away too rapidly and open up paths of infection. Mr Waggett's suggestion as to finger exploration was rational. In reply to Dr William Hill, he said that he had not found that frontal lobe abscesses did any worse than those in other situations, but rather the contrary, they probably took longer to diagnose. In reply to a question by Dr Coates, he said that he had very rarely seen multiple brain abscesses except in museums. He did not agree with dispensing with the use of drainage tubes, but he had no experience of the gauze method, the frequent pulling away of the gauze would be liable to damage the wall of the cavity, it had been tried many years ago in the peritoneal cavity and abandoned.

EAR INJURIES FOLLOWING SKULL FRACTURES

Mr E D D DAVIS described the various lines of fracture in the base of the skull, the majority of which involved the middle cranial fossa. It was nearly always the middle ear which was involved, and very rarely the internal ear. The external auditory meatus was, however, quite frequently injured, especially in fractures through the Glaserian fissure. In some cases middle-ear deafness resulted merely from the extravasation of blood into the middle-ear cavity, and the blood could sometimes be seen at the Eustachian orifice in the nasopharynx. Taking a series of skull fractures, he found that haemorrhage from both ears showed a mortality of 66 per cent, whereas in cases of haemorrhage from one ear the mortality was only 39 per cent. The average mortality in all cases of fracture of the base of the skull was about 40 per cent. When the facial nerve was paralysed the injury usually occurred in the neighbourhood of the geniculate ganglion, and these patients eventually recovered. Any improvement in the hearing function followed in about eight weeks, after that time not much improvement could be expected. Injury to the internal ear was very rarely seen clinically, probably because all such patients died owing to the severity of the concussion. Treatment consisted in rest and cleansing the meatus. Any discharge from the ear should be mopped up and skin irritation carefully guarded against. No ear drops or mops should on any account be introduced into the meatus owing to the danger of secondary infection.

accurring. If suppuration supervened vigorous methods of treatment, including early drainage of the antrum if involved, must be at once instigated.

RADIUM TREATMENT OF MIDDLE-EAR DEAFNESS

Dr WILLIAM HILL read a short paper on the question of treatment of middle-ear deafness and lachrymian catarrh resulting in deafness, by means of the application of radium. In his cases he irradiated only one ear, using the other ear as a control. He had treated 47 cases, all of which had reached a stationary condition so far as other more recognized methods of treatment were concerned, 9 cases had shown substantial improvement and 7 slight improvement. He gave two to four applications of 50 to 60 millicurie hours. After careful examination and treatment he was quite satisfied that in certain cases he obtained substantial improvement.

SECTION OF TUBERCULOSIS

Thursday, July 26th

SURGICAL PROCEDURES IN PULMONARY CASES

THE chief impressions left by the discussion on the after-effects of surgical procedures in cases of pulmonary tuberculosis, which took place in the Section of Tuberculosis at Cardiff on July 26th, were that the physician was being ousted from his last stronghold, the chest, and that the success recorded by the surgeon in this region might justify his admission at an earlier stage of the disease. The former of these impressions was emphasized by Dr CECIL WALL, who thought that in the future the distinction would not be between physician and surgeon, but between practitioner and chest specialist.

Mr TUDOR EDWARDS, in opening the discussion, dealt first with the choice of cases, which should be those of chronic third stage type, with little or no activity in the "better" lung. Old cases of artificial pneumothorax, in which refill was no longer possible, were suitable for thoracoplasty, as also were those cases in which fluid developed and became purulent. Infected tuberculous empyemata, in which delay might lead to lardaceous disease, should be treated by thoracoplasty as soon as possible. Although early cases should be given extended trial of other medical measures before operation was considered, Mr Tudor Edwards thought that there was a tendency to wait too long. He endeavoured, in his operations, to obtain adequate collapse of the whole lung, proceeding first by phrenic evulsion, and then, a week or two later, by thoracoplasty, from the first to the tenth rib posteriorly, in two stages. Localized collapse could be obtained by phrenic evulsion or by pneumolysis. The chief value of the latter operation was, he thought, for a residual cavity left at the apex after thoracoplasty. Mr Tudor Edwards then gave figures of the results of his operations, for which it appeared that over 50 per cent of the patients treated by thoracoplasty were cured or much improved, while less than 7 per cent died within three weeks of the operation.

Dr F G CHANDLER called attention to the natural instinct of the physician to consider the operative risk to his patient and the possibility of after-pain and discomfort. In some cases it was necessary that the patient should decide the question of operation for himself, since, if he knew the risk, he might prefer to die. Dr Chandler regarded intrapleural pneumolysis as unsatisfactory. Phrenic evulsion involved little risk, and in basal tuberculosis, and as an accessory to incomplete artificial pneumothorax, was very useful. Apicolysis and pneumolysis had great possibilities, while thoracoplasty had brilliant and lasting results in the hands of a properly trained surgeon. It demanded perfect technique. In a series of patients operated on it had been found that over 42 per cent were fit for work two years after the operation, while of a similar series not operated upon only 11 per cent were fit for work. Dr Chandler concluded by deploring the apathy towards modern advances in the treatment of pulmonary tuberculosis which he believed to exist.

Subsequent speakers described thoracoplasty as a serious or desperate operation, but Mr WILLIAM ANDERSON

suggested that it gave a chance to cases otherwise hopeless, while Dr FENWICK JONES thought that suitable cases should be tackled much earlier than was done at present. He gave statistics of twenty-five operations performed at the North Wales Sanatorium. Dr D A POWELL believed that ultimately the results of thoracoplasty would surpass those of artificial pneumothorax. Dr H MORRISTON DAVIES showed photographs of patients who had undergone the operation, which made it clear that the patients had not been crippled, that when dressed they showed no deformity, and that there was no dropping of the shoulder and no scoliosis. He pleaded for the introduction of surgical facilities into sanatoriums, and said that while the Welsh National Memorial had set the example in the Principality the only sanatorium he knew of in England which had an operating theatre was the Cheshire Joint Sanatorium.

Mr TUDOR EDWARDS, in his reply, stated that after-pain from the operation was due purely to bad technique. He felt there was no justification for describing the operation of thoracoplasty as desperate, and he mentioned that at the Ventnor Sanatorium a theatre had already been built. Dr CHANDLER expressed the hope that surgeons who meditated taking up the operation would serve an apprenticeship under those who had developed it.

THE GENERAL PRACTITIONER AND TUBERCULOSIS

THE discussion on tuberculosis as seen by the general practitioner was enlivened by an opening paper read by Dr ANGUS KENNEDY, which was described by Dr POWELL as a salutary cold douche. His thesis was that the claim that the lower mortality from tuberculosis was the result of preventive measures, mostly undertaken during the past twenty-five years, would not bear scrutiny. The present expenditure of labour and money was not justified by the results. An examination of the mortality from the disease during the last two hundred years showed that it was 14 per cent in 1721, 25 per cent in 1821, 12 per cent in 1871, and that since then there had only been a reduction of a further 3 per cent. The great reduction was in the time of our grandfathers, before preventive measures were thought of. Dr Kennedy considered the fall in the mortality since 1821 to be due to lessened virulence of the bacillus and increasing resistance of the race, and illustrated his point by referring to the intense susceptibility to the disease shown by negroes in the East End of London. He thought that the disease could only be eliminated by cultivating the eugenic conscience.

Dr R CAMERON (Cardiff) read a paper on the problem of early recognition of tuberculosis. He had investigated the existence of the disease in Cardiff, and found that phthisis alone accounted for roughly 20 per cent of all the deaths between 15 and 65 years of age. Over 50 per cent of the patients slept in contact with other persons. He enumerated the symptoms to be looked for in early cases under Pottenger's three headings—pulmonary, reflex, and toxic— and said that he regarded the finding of the bacillus as the only real proof of tuberculosis. Diagnosis by tuberculin did not give reliable results. In his opinion Dr J R GILLESPIE did not support him, as he had found the subcutaneous test very valuable, though the skin test was useless. He began with 0.0002 c.c.m., and gave six doses, doubling the dose each time before pronouncing the case non-tuberculous. Dr AMBROSE OWEN gave some interesting statistics of cases which had occurred in his practice, and Dr W T HALL asserted that among his patients the best results were obtained in those who had been through a sanatorium course. He did not believe that tuberculin could be used safely by the general practitioner in the patient's home, and reliance had to be placed on treatment by drugs. Dr HOPKINS ASHMORE thought that dust caused the spread of the disease, and suggested enumeration of all dust collected, but Dr MATTHEWS said that analysis of the dust from the waiting room of a tuberculosis institute had not shown the presence of living bacilli. Infection was probably from droplets of sputum. He had found that the reaction to tuberculin used for diagnosis, differed in urban districts from rural. Urban children of 10 to 15 years reacted very much more

frequently than rural children, while a higher rate of incidence of the disease in children giving a positive reaction was seen in the country.

Dr CAMFRON, in his reply, deplored the lack of hospital accommodation for advanced cases of tuberculosis.

SECTION OF MEDICAL SOCIOLOGY

Friday, July 27th

THE FALLING BIRTH RATE

THIS year's discussion, on the falling birth rate, in the Section of Medical Sociology raised many interesting questions. What are the causes of the fall? The openers of the discussion were hardly agreed. Professor W. J. ROBERTS (Cardiff), on the economic side, had no belief in Malthus's laws of population. He thought the importance of the economic motive should always be borne in mind. Inquiry should be made more closely into the lives and economic conditions of various classes, and he suggested that the medical practitioner might render important help by inquiring of his patients what they thought and what were the motives for their conduct. People conducted themselves under the limitations of their social position and of their knowledge. Some were more inclined or better able to follow medical advice on the matter. In his opinion overcrowding was an argument which might be used to prove too much. There was no evidence of real overcrowding in this country, and on halving the population of Cardiff it might be found that the apparent overcrowding was not relieved. Similarly the old solution of the problem by emigration was not valid, and economic dogmatism on the matter was not possible.

Dr F. A. F. CREW (Edinburgh) elaborated opinions which he had formed from his biological investigations of mice, drosophila, and other organisms. In drosophila there was an optimum density of population, above and below which there was a lower reproductive rate. The harmony between a limited area and its supplies was maintained by restricting fecundity. The human being, he thought, was now approaching the end of a birth rate cycle, but the distinction of the factors in producing it was difficult. A rising birth rate heralded an extension of the conquest by man over his environment; a falling rate indicated that in a particular area he was permanently or temporarily imprisoned. The birth rate would not rise again until the factors overriding the inherent tendency to increase were recognized and removed. Among factors making for increase, Dr CREW mentioned the presence in a community of "multiple birth" stocks, the possibility that *mittelschmerz* in females might indicate more intense sexual life, and length of life, which was an inherited character. A fall occurred in discontented and discouraged populations, in whom it was interesting to note a degeneration of the maternal instinct. Immigration among drosophila led to a fall of population. The root of the matter in the human being was probably to be found in social conditions. Among the socially unsuccessful the only outlets of nervous release were excessive drinking and sexual over-indulgence. In such classes the reproductive rate would be high, social advancement implied other outlets and a lower reproductive rate. But birth control, while preventing the birth of individual babies, did not have much effect on the gross birth rate.

SIR THOMAS HORDER doubted whether the falling birth rate came within the province of the medical practitioner, though greatly concerning the biologist and the economist. These two, together with the physiologist, the biochemist, and the eugenicist, must solve many problems before the doctor could prescribe appropriately in the matter for his patients. He should not lend himself as an ally to the eugenicist until many of these problems had been solved. The doctor had a sanction for individual therapeutics but hitherto he had not sought to influence men and women on matters of principle. He had kept clear of propaganda. Lady BARNETT was of opinion that the falling birth rate was a matter which should concern general practitioners. It was important that they should take a wider view of matters which affected the health of their patients, and be in a position to tell them the real facts about birth control,

the average frequency of births to married couples, and other similar matters. In some cases it was their duty to teach the advantages of normal marital relationships, in others to do all in their power to help patients to avoid pregnancy. If it was thought that medical practitioners were unfit to deal with the question, arrangements should be made for teaching medical students the subject and their responsibility therein. Dr WILLIAM COLLIER (Oxford) suggested that the medical profession had helped to maintain the population by saving much infant mortality, but he was chiefly concerned that the profession should give advice in birth control for which purpose he advocated the establishment of birth control clinics. Dr LETITIA FAIRFIELD thought that the falling birth rate was due to wide causes, and not to individual action. These causes might be classified as voluntary and involuntary. She objected to the eugenicist putting upon the doctor his so-called laws. She emphasized the importance of motivation, and the human being's view of life. Jews and Roman Catholics were fertile because of their outlook on life. Dr BINNIE DUNLOP expressed the opinion that couples in the poorest classes should be encouraged to have not more than two children. In these hard times, with many adults out of work or on insufficient wages, a very low birth rate was especially desirable. Mrs NEVILLE ROLFE regarded emigration as a cure for many social difficulties, but protested against the failure of local authorities to train and equip an equal number of girls with the boys. Dr N. E. WATERFIELD pointed out that the medical man had some responsibility in the matter, and some influence in individual cases in which he was consulted. Absolute sterility was, in his opinion, always involuntary, but small families were usually the result of contraceptive methods.

Professor ROBERTS, Dr CREW, and Lady BARNETT replied to some of the criticisms which had been made.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DIATHERMY FOR CANCRUM ORIS

CANCER ORIS is fortunately now a rare condition at least in this part of England. Nevertheless examples turn up from time to time renewing interest and arousing responsibility. A close association with a considerable number of cases during the last thirty years has taught me how very serious the prognosis usually is, and how inefficient most of the methods of treatment. On March 30th of this year, a child suffering from this condition was admitted to the Royal Victoria Infirmary under my care, she was a light-haired little kiddie, 4 years of age, and looking as though of very poor resisting powers. There was a large black patch of gangrenous tissue about the size of half a crown over the horizontal ramus of the lower jaw on the right side, and this was surrounded by a zone of acute inflammation, with swelling of the side of the face and neck. At one point the edge of the gangrenous area had separated, and there was a small amount of very offensive discharge. The buccal cavity was not infected. The temperature was 102.8° and the child was toxic and profoundly ill. While pondering over the best method of treatment, it suddenly occurred to me that complete excision by the method of diathermy might cut short the infective gangrenous process, and I determined to try it. Under a general anaesthetic the diathermy knife was applied about half an inch from the edge of the black mass to include the spreading edge, and a free circular excision was carried out. To remove all the dead tissue it was necessary to go right down to the bone and when the mass was separated from the latter the horrible sickening odour of the roasted gangrenous tissue almost overcame me. After this complete excision about 1½ in. of the body of the jaw lay exposed at the bottom of the wound and subsequently necrosed. The area was packed with gauze and external dressings applied. The condition of the patient under the anaesthetic gave much cause for anxiety, but she soon picked up, and almost from that moment commenced to make a satisfactory recovery. The temperature fell at once and remained at

normal, with the exception of one or two days at the end of a fortnight when there was a mild outburst of surrounding inflammation, but without any of the characteristics associated with infective gangrene. During the sixth week the patient was able to leave hospital, and progress continued uninterruptedly afterwards. On July 18th the sequestrum was obviously loose, and was lifted out by the family doctor. Afterwards the area soon healed, leaving a surprisingly small scar. This is the first occasion on which I have used diathermy for acute gangrenous necrosis of this kind, but the result has been so satisfactory as to encourage me to employ it in future. It is because I think that this method is well worthy of extended trial that I send you this brief record of a single case, and in the hope that others may have a similar fortunate experience, but whatever the results, it is well that they should be known to the profession.

G. GREY TUNNFR, M.S., F.R.C.S.,
Newcastle-on-Tyne, Professor of Surgery, University of Durham

DRY CUPPING IN CHRONIC EMPYEMA

The following is, I believe, an original method of dealing with relapses from which most chronic empyema cases suffer from time to time.

A man aged 32 with a sinus of the chest wall following three operations for empyema, consulted me because the discharge had ceased for some days and he had symptoms of toxæmia. X-ray examination revealed an encysted collection of pus, with marked pleural fibrosis. I introduced sinus forceps and a probe into the sinus to a depth of 5 inches, but pus could not be found as the sinus was tortuous. I then inserted a fine rubber tube into the sinus to the same depth and having vaselined the skin I applied a dry cup in the usual way. About five seconds later the patient felt something give in his chest, his dull pain there immediately departed and the cup was filled with pus.

In this manner about 200 c.cm. of pus was evacuated and in a few hours the patient felt better in every way. Subsequent cuppings for the next two days exhausted the supply of pus, the symptoms of toxæmia rapidly abated. Direct suction on the tube with a syringe was useless, as, being of necessity a fine one, the tube would have collapsed.

The treatment is simplicity itself, notably dramatic, and efficacious, and the patient was discharged from hospital after six days, quite fit, and intensely grateful for having been saved the ordeal of a further operation.

I am indebted to Dr. Lind Walker for permission to publish this case.

ROBERT A. CAMERON, M.B., Ch.B.
Senior House-Surgeon, Royal Infirmary, Doncaster

AN UNUSUAL CASE OF A RUPTURED ECTOPIC GESTATION

The following case is of unusual interest, since it illustrates that rupture of the tube in an ectopic gestation may occur (1) as late as the fourth month of pregnancy (2) without the slightest evidence of external (vaginal) hæmorrhage, (3) without the characteristic features of internal hæmorrhage save a slightly raised pulse rate (84) and (4) with the gradual development of peritonitis with equivocal physical signs.

A primipara aged 20 had had amenorrhœa for four months and at 6 o'clock on the evening of June 20th was seized with sudden pain in the back and right lower abdomen. She managed to carry on for about an hour but was ultimately compelled to take to bed. I was called to see her about 10 p.m. The patient was pale, her pulse was 84, she had not vomited, there was no respiratory distress and no sweating, but the patient bore an anxious expression which did not seem to fit in with the clinical findings. There was abdominal tenderness distributed all over the abdomen but particularly in the right flank. The patient was mentally alert and capable of answering any questions asked.

A somewhat tentative diagnosis of ectopic gestation was made on the grounds of amenorrhœa, the pallor, the slightly raised pulse rate and the abdominal tenderness.

On opening the abdomen at the Merthyr General Hospital the peritoneal cavity was filled with blood and blood clot, the left tube was ruptured about midway between the uterus and the infundibular extremity and a foetus about 8½ c.cm. was lying freely in the abdominal cavity.

The case illustrates certain points which are against the recognized textbook descriptions of this not uncommon catastrophe, and should be kept in mind by practitioners when dealing with an 'acute abdomen'.

I wish to thank Mr. S. C. Cresswell for permission to report this case.

CLINICAL AND SCIENTIFIC PROCEEDINGS

STAFFORDSHIRE BRANCH

The Fallacies of Negative Findings

At the annual general meeting of the Staffordshire Branch, held on July 19th, the President, Dr. G. H. SOWRY, read a paper on "The fallacies of negative findings."

Dr. Sowry showed the pitfalls into which one might fall by arriving at a purely negative diagnosis, and emphasized the importance of assessing, as accurately as possible, the pathological condition actually present. In this connexion he mentioned a consultation which he had recently attended regarding a case of suspected small pox in which the consultant had stated his belief that the case was not small-pox, but, having gone thus far, said that as well as arriving at a negative diagnosis they must also make up their minds as to the disease from which the patient was in fact suffering. Only thus, by arriving at a positive diagnosis, were they justified in being sure that the case was not small-pox. Dr. Sowry instanced cases of tonsillitis in which the negative diagnosis of "not diphtheria" was reached, but which investigations pushed to the length of arriving at a positive finding would have revealed as cases of scarlet fever much sooner than the true diagnosis was, in fact, made.

In the case of sputums yielding negative results with regard to tubercle bacilli, Dr. Sowry pointed out that one negative examination, or, indeed, five or six such examinations, did not entitle one to say that the case was not one of pulmonary tuberculosis. In instances of suspected pleural effusion the failure to find fluid on one puncture might be due to the smallness of the amount of fluid, or to the needle being introduced into the lung or even into the liver, so that a negative result of a pleural puncture did not exclude pleural fluid. With regard to the Wassermann reaction, Dr. Sowry mentioned several cases in which this reaction had been negative, but the clinical picture being that of specific disease, and the cases reacting dramatically to antisyphilitic treatment, they were almost certainly instances of syphilitic disease. Many diabetics might at particular times of the day pass urine in which there was no sugar, one could place reliance upon the negative results of an examination for sugar only if the sample examined had been taken from a mixed specimen of a twenty-four-hour output. Dr. Sowry reiterated the well-known fallacy attaching to negative results in the examination of throat swabs taken from suspected cases of diphtheria, and he also indicated the fallacies attaching to negative results (achlorhydria) obtained in the examination of fractional test meals.

The lecturer next discussed examinations by x-rays, and, while he paid a tribute to the extreme utility of such examinations, he emphasized the pitfalls which had become apparent to him personally. Thus a gastric or duodenal ulcer, though present, might not show up on an x-ray photograph representing an antero-posterior view, particularly if the ulcer were situated, in the case of gastric ulcers, at some distance from the anterior or posterior curvatures. In order to show gastric ulcers situated at places other than in the neighbourhood of the curvatures it was necessary to take a lateral view. In cholecystography, after the exhibition of an opaque dye, a negative result might be due to faulty absorption of the drug, and need not necessarily be associated with the gall bladder conditions which, if present, would give a similar result. Dr. Sowry instanced the accidents which might arise in cases of suspected malignant disease of the lower alimentary canal in which the negative result of a digital examination had led to a reassuring diagnosis, and he emphasized that the disease could not be excluded in the absence of a sigmoidoscopic examination, and, if that should prove negative, of an x-ray investigation of a barium enema.

Dr. KING ALCOCK moved, and Dr. MENZIES seconded, a vote of thanks to Dr. Sowry for his excellent paper.

Reviews.

ADDRESSES IN SURGERY

THE President of the Royal College of Surgeons of England has collected a number of his orations, lectures, and addresses and published them in a volume entitled *Addresses on Surgical Subjects*.¹ Sir BERKELEY MOYNIHAN is well known as a brilliant orator who does not suffer by comparison with Sir James Paget. A number of these addresses are reprinted from our pages, and several have furnished us with themes for leading articles. Highly as we have valued them, we were better able to appreciate the wide range of knowledge and the versatility of their author when we re-read them now in the volume which has just appeared. For the audiences to whom they were addressed were as various as the subjects of the orations and their treatment, and whether it was a popular lecture on cancer delivered in the Hastings Hall of the British Medical Association, or a Mitchell Banks Lecture packed with statements of physiological and pathological fact and with closely reasoned arguments based upon them, each is in its way a model for imitation, and must have been a delight to those who had the good fortune to hear it. Sir Berkeley Moynihan is a surgeon who sets very high ideals before himself and lays claim—and, as we think, makes good his claim—to a high place for surgery among the sciences, a place which, as he remarks, the Royal Society is not disposed to give it, seeing that at the present time no practising surgeon as such may write the much prized letters "F.R.S." after his name, although we are proud to reckon Sir Arthur Keith among the Fellows of the Royal College of Surgeons. But Sir Arthur Keith earned his fellowship of the Royal Society, not as surgeon, but as an anatomist, pathologist, and palaeontologist. In the first address in this book the Hunterian Oration of 1927, on Hunter's ideals and Lister's practice, Sir Berkeley Moynihan playfully prophesies that hereafter the spirit of our present beloved conservator will conduct the ghost of John Hunter round his own museum and introduce it to the wonders of the microscope. In the Harveian Oration to the Medical Society of London a very important matter is duly insisted upon—namely, that a surgical operation should be only one incident in a long series of events stretching between illness and recovery, and that the cure and science of the surgeon must be exercised long before and perhaps also long after the actual operation.

To the American College of Surgeons in 1920 Sir Berkeley Moynihan addressed a glowing eulogy of John B. Murphy of Chicago, whose memory he held up to his audience as one that would endure among those of the supremely great men in medicine through all generations. This occasion was also seized upon to deliver a brilliant sketch of the history of medicine, a subject which also occupied a prominent place in the presidential address to the Science Masters' Association in 1925. In the "role of a physician doomed to the practice of surgery," to use his own words, our author recapitulated the enormous benefits which surgery and the patient had received from the discovery of x rays and the elaboration of technique and apparatus in their use, not only as an aid to diagnosis, but as a therapeutic agent, in which latter capacity he urges its employment immediately after the excision of certain cancers, such as those of the breast. "The Contributions of Leeds to Surgery" was a pious offering to his Alma Mater by one of the brilliant company of Leeds surgeons whom the speaker recalled to notice in the coming of age address in 1924. Leeds Infirmary, which is, of course, many times as old as the University, has been fortunate in its medical staff, beginning with the Heys and continuing to the present day. The addresses delivered during the Lister centenary celebrations in 1927 were noticed in our columns at that time, except one which is unusual in its occasion, for it was spoken into a wireless receiver and transmitted to the world by the British Broadcasting Corporation. The address on perforation of gastric and

duodenal ulcers, which was delivered in honour of Professor Raffaele Bastianelli, covers in a condensed form much of the results of an almost unique experience of such accidents, considered with ripe and acute judgement. All abdominal surgeons may profit by it. In a short address to the Mental Diseases Section at the Edinburgh Meeting of the British Medical Association, on the relation of abhorrent mental states to organic disease, Sir Berkeley Moynihan once more recalled the debt due to Dr. William Hunter for his long-unrecognized work on focal sepsis, especially of the teeth and gums and of its great pathological and surgical importance. In the two last articles in the volume, on acute pancreatitis and on the gall bladder and its infections, the author is at home in a realm which he has largely made his own. These will both repay study, and the last one will require careful perusal if the reader is to profit by its rather intricate pathology and the closely reasoned arguments based upon it. This article is illustrated with reproductions of radiographs and of microscopic sections, which are very instructive.

We hope that we may be permitted to make one reflection on this collection of addresses on surgery by an admitted master of his art. Omitting the more general topics of discourse, the surgical conditions dealt with are almost all to be found in the abdomen, into which cavity surgery some time ago plunged and from which it nowadays but rarely emerges, to judge only by publications and the programmes of surgical meetings. We infer from these facts that indeed the subject of abdominal surgery is so vast and so intricate, becoming more and not less complex as time passes and experience accumulates, that even the most comprehensive intellects have little time to spare for the consideration of other regions of the body.

BEDSIDE AND LABORATORY

THE laboratory methods of the Vienna clinics,² by Professors BARRENSCHEN and WILLHEIM, in collaboration with nineteen other teachers, is written, as the title evidently implies, partly with a special object—namely, to exhibit the relation obtaining between the clinician and the laboratory worker in the Vienna school. It is well known that in some schools the laboratory worker was at first regarded with a certain degree of indifference and even coldness by the clinician, the prejudice often extended beyond the walls of the hospitals, and those medical men who happened signally to favour laboratory methods were apt to be caricatured as "test-tube doctors." Opinion has altered, at least within the profession: the value of laboratory work in diagnosis and prognosis is now fully recognized, and although intuition and the clinical instinct are still felt to be of supreme importance there is a desire to base every diagnosis on objective findings as far as possible. Although, owing to the special and complicated technique of the work involved, the laboratory must necessarily remain as a separate department from the clinic, there can be no cogent reason why the two should not work hand in hand—that is to say, the clinic should make every possible use of the laboratory for the furtherance of medical science, consistent with the interests of the individual patient. It is the boast of the authors that the Vienna school has always made it a fundamental principle to refuse strictly scientific methods into clinical work—to combine clinical intuition with scientific penetration such as the tradition of the school. The present volume exhibits the methods actually in use in the Vienna school, the work is therefore incomplete in the sense of not mentioning all possible methods—selection was inevitable. On the other hand, the scope of the work is wide, including not only the usual methods of blood examination, bacteriology, serological diagnosis, and the analysis of secretions, exudates, and excreta, but many special procedures, such as the meostagmine reaction for carcinoma. If the book may be taken as a measure of the encouragement given by the clinician to the laboratory worker, the Vienna school is to be congratulated on the happy relations existing between the two departments.

¹ *Addresses on Surgical Subjects*. By Sir Berkeley Moynihan. Bart., President of the Royal College of Surgeons of England. Philadelphia and London, W. B. Saunders Company, 1928. (Med. 8vo pp. 348. 8 figures. 22s. net.)

² *Die Laboratoriumsmethoden der Wiener Kliniken*. Herausgegeben von H. K. Barrenschén und R. Willheim. Leipzig und Wien, F. Deuticke, 1928. (Sup. roy. 8vo pp. xxv + 800. 104 figures. 19 plates. 34s.)

BRUMPT'S PARASITOLOGY

PROFESSOR BRUMPT'S well known *Precis de Parasitologie*,³ of which a fourth edition now appears, really needs no introduction. It is one of the excellent series published by Masson et Cie, but in its remodelled form, with 236 more pages of text and 89 new figures, this volume must be considered as a very complete textbook of parasitology rather than a précis. It will find a place, as did the preceding edition (1922), in the library of everyone interested in the subject. It is practically double the size (and double the weight) of the other members of the series and its 1,452 closely printed pages of small type make a volume which, we may be allowed to suggest, would in future editions be better if divided into two. The book is so arranged that each parasite is studied as it falls into its natural order, with preliminary notes on its classification and relationship to others. A description is given of each species, its life-history, and the part played by it in human disease, with a short account of disease distribution, symptomatology, diagnosis, and treatment. The work thus constitutes a complete textbook covering a very wide ground, and will undoubtedly continue to prove of great value to the student of parasitology. Recent additions to knowledge have largely been incorporated in the text, and where this has not been possible the book has been brought quite up to date by a system of copious footnotes with references to authors, among whose names English workers bulk very largely. It is manifestly impossible, and, moreover, unnecessary, to give more than this brief general notice to a book of such large dimensions.

IONIZATION FOR NON-SUPPURATIVE OTITIS

A REVIEW of the physical laws concerned in the study of ionization, illustrated by a series of experiments, introduces a small book,⁴ by Dr LANDRY and Dr FRANQUET of Rheims, on a method of treating non suppurative otitis. Some of these experiments, designed to demonstrate the passage of ions, are at once simple and ingenious. From these the authors conclude that the medicament chosen can be introduced into the tissues in a nascent and perfectly pure condition. The choice of medication is based partly on an experiment of Gouget, who showed that it is impossible to produce atheroma experimentally in rabbits by the injection of adrenaline after a preliminary treatment with silicates. The action of silicon in the tissues is a perpetual struggle with the carbonates, and prevents their fixation. The authors claim that the introduction of the ion represented by SiO_2 into the tympanum relieves the tinnitus associated with sclerotic changes in the middle ear. They have also experimented with sodium chloride, potassium iodide, and calcium salts, the last especially in cases of otosclerosis. They are careful not to claim too much for the method and to limit themselves to experimental and clinical observations. They have, however, clearly established a case for further study of this form of treatment in a class of patients whose symptoms are usually refractory and distressing.

FORENSIC MEDICINE

THE second edition of Professor SYDNEY SMITH'S *Forensic Medicine*⁵ will be especially welcome to the students of Edinburgh University, where he now holds the chair of forensic medicine. Since the first edition of his book Professor Smith has undertaken the revision of Taylor's *Principles of Medical Jurisprudence*, in which task he has had the able assistance of Mr Cook of the Middle Temple as co-editor, and the success which has attended his efforts in that direction has been reflected in the second edition of his own book. This book is already so well known that

it requires no recommendation. Based on the Edinburgh teaching, where Professor Smith received his early training, it has been elaborated in the light of the wide practical experience acquired by the author whilst in Egypt. The text of the new edition is naturally to a large extent unaltered, but several changes in the law have called for attention, and the few errors which are apt to creep into a first edition have now been eliminated. There is a slight increase in the amount of subject matter, and we are pleased to see that the illustrations, which are excellent, have been considerably increased in number. The student will find this excellent book a most interesting and comprehensive work, easily read, full of detail, yet at the same time not too expanded for his purpose. It is a book on which thorough reliance can be placed, and one which the student will retain and consult when in practice.

BREND'S *Handbook of Medical Jurisprudence and Toxicology*⁶ is already well known and widely used. This new (sixth) edition has been brought fully up to date, and includes references to the latest Acts, regulations, and decisions. The text is easily read, and the descriptions of all branches of medical jurisprudence are full and adequate, except in regard to the procedure in criminal cases and the investigation of sudden deaths. This differs in England and Scotland, and it would have been an advantage to students in Scotland, where the handbook is widely read, if the account had included a description of the procedure in that country. Dr Brend's little volume can be strongly recommended to the student, who will find no better book for his purpose.

POTTED PHYSIOLOGY

THE publishers of a popular series of synopses of various branches of medical science have now added physiology⁷ to their list. The joint authors are Dr A. RENDLE SHORT and Mr C. I. HAM. Educationists may be tempted to deprecate the circulation amongst medical students of such "crum books", but the condemnation is probably unsound. Such books as these have a very obvious purpose. They comprise a series of headings, subtitles, and terse notes, which, at the worst, may be accepted as more judicious, better balanced, more consecutive, and freer from misinterpretation than are the notes which the average student can hope to assemble from the lecture courses he is expected to attend. If he will take this skeleton of physiology, as he would take his own notes, and clothe its dead bones with living description and argument, he will have gone some way towards an understanding of his subject. He will have had to read deeply in the excellent textbooks of physiology which are available, and he will (if blessed in his teachers) have been able to take full profit from his lectures.

The authors, in a preface, express the hope that their book may be of value also to "practitioners who wish to keep abreast of modern physiology" and, as an aide-memoire, to our brethren who lecture to classes. The library of physiology is not so bare that we can be content to offer to these the dry bones of knowledge.

ANNALS OF MEDICAL HISTORY

THE first of the eleven main articles in the summer number of the *Annals of Medical History*⁸ is on "The Beginnings of American Physiology," by Dr Walter J. Meek, and is illustrated by seven portraits, two of which—those of the well-known William Beaumont and the prolific Rohley Dunglison (1792-1869) who analysed the gastric juice of Alexis St. Martin and whose medical dictionary ran through twenty-three editions—also do duty on the cover.

³ *Precis de Parasitologie*. Par E. Brumpt. Quatrième édition entièrement remaniée. Collection de Précis Médicaux. Paris: Masson et Cie (5 x 7 1/2 pp. xiii + 1452. 785 figures. 6 plates. Paper cover. 80 fr. bound. 100 fr.)

⁴ *Ionisation dans les Otites moyennes non suppurées. Méthode et Résultats*. Par le Dr M. Landry et le Dr René Franquet. Paris: Vigot Frères (44 x 7 pp. 110. 8 figures. 8 fr.)

⁵ *Forensic Medicine*. By Sydney Smith M.D. Ed. DPH. With an Introduction by Professor Harvey Littlejohn. F.R.C.S. Ed. F.R.S.E. Second edition. London: J. and A. Churchill. 1928. (Demy. 8vo. xv + 662. 166 figures. 24s. net.)

⁶ *Handbook of Medical Jurisprudence and Toxicology*. By William A. Brend M.D. B.Sc. London: Sixth edition revised. London: C. Griffin and Co. Ltd. 1928. (Fcap. 8vo. pp. xiii + 327. 10s. 6d. net.)

⁷ *Synopsis of Physiology*. By A. Rendle Short M.D. B.Sc., F.R.C.S. and C. I. Ham M.D., B.Ch., M.R.C.S., L.R.C.P. Bristol: J. Wright and Sons Ltd. London: Simpkin Marshall Ltd. 1927. (Cr. 8vo. pp. 253. 10s. 6d. net.)

⁸ *Annals of Medical History* (Summer Number 1928), vol. x. No. 2. Edited by Francis R. Packard M.D. New York: Paul B. Hoeber, Inc. London: Baillière Tindall and Cox. 1928. (8 1/2 x 12 1/2. pp. 111-212. illustrated. Subscription in Great Britain £2 2s. a volume of four numbers.)

and as frontispiece There are two rather remarkable portraits of J. Call Dalton (1825-1889), who studied the biliary secretion by means of a biliary fistula and was the first in America to illustrate his lectures by experiments on living animals. Dr B. Barker Beeson contributes an intimate account of Jean Martin Charcot (1825-1893) whose rise from the son of a coachbuilder to his eventual pre-eminence was the outcome of a great ability. His profile has been compared to that of Dante, Napoleon, and a Roman senator. The pediatric activities of the three generations of the Meigs (1792-1912) are recounted by Dr A. Levinson of Chicago. In his essay on the episode of St. Thomas Browne and the witches Dr J. H. Lloyd concludes by expressing a regret that belief in witchcraft did not find a place in the famous "Vulgar Errors." There are two articles dealing with Samuel Pepys, Dr R. L. Pittfield gives a short account of his oculist D'Aubegney D'Urberville and his family, and Dr Jean Broadhurst contributes "Pepys with Pepys at Hygiene and Medicine." The life of Alexander Garden, M.D., F.R.S., a colonial physician and naturalist of Charleston, who was a correspondent of Linnaeus, is supplied by Dr P. C. Jenkins, and Dr A. J. Buchanan writes on the solution and works of J. G. A. Lugol (1788-1851). Shakespeare's knowledge as a neuropsychiatrist is analysed by Dr G. E. Price in an article brimming over with quotations. Medical terminology is discussed in a specially interesting manner by Dr Edmund Andrews, who traces the origin of medical words and incidentally gives much curious information. Ptolemy in a Pleistocene wolf is the subject-matter of Dr Roy L. Moodie's twenty-second study in Palaeopathology. There are two attractively written editorials of a centenary character by Dr FRANCIS PICKARD on Marcello Malpighi (1628-94) and by Dr F. H. Garrison on Emil Neugebner (1827-1895).

NOTES ON BOOKS

THE volume of short essays entitled *Coloured Thinking*, the subject of the first essay by Dr FRANK HARRIS contains a number of reflections on scientific subjects somewhat in the nature of asides from the main path of science. Gleanings from the lives of scientists showing their delight in discovery—science and character—the beautiful in science—such are some of the subjects dealt with in this interesting little volume. Other articles have a historical or antiquarian leaning, such as those on the origin of certain scientific terms on the influence of Italy and on biology in Shakespeare. 'Coloured thinking' strictly speaking is that peculiar tendency exhibited by some individuals of colouring all their thoughts—Monday will be blue Tuesday yellow for example. But the author evidently implies a wider meaning to the term, and would have all scientific thinking coloured with an appreciation and reverence for the beautiful all scientific achievement coloured with modesty and all thought and action coloured with a tone of refinement.

Those who wish to study the eugenic views on medical examination before marriage will find them set forth in *L'Examen médical en vue du mariage*.¹⁰ The book is mainly a collection of addresses delivered before various eugenic conferences by doctors from several countries with a summary of the general conclusions by M. L. March, a vice-president of the French Eugenics Society. In several countries there has been legislation on the health of those about to marry, and in several States in the U.S.A. attempts have been made to demand pre-nuptial certificates. It appears, however, that it has been found impossible to enforce such decrees and the writers in the book before us seem to agree generally that milder methods must be used. Thus in Holland the registrars deliver warning literature to the betrothed. In Scandinavian countries marriage of the mentally affected and of those suffering from epilepsy or contagious venereal disease, is strictly forbidden. But in these and most other countries it has been decided that obligatory certificates before marriage are inadvisable. The majority of the authors agree that medical examination should be promoted by propaganda through the press by means of handbills and by meetings, that free matrimonial clinics should be organized, and that laws against the communication of infectious disease should be rigorously enforced. In fact, the

book impresses us by the modernization of its proposals, as compared with the claims for the studious production of ideal citizens which so often seem to be made by individual eugenicists.

Crawford W. Long and the Discovery of Ether Anesthesia,¹¹ by Mrs. FRANCIS LONG TAYLOR, the daughter of the young medical man who, when only 26 years of age first employed ether as an anesthetic on March 30th 1842, is an expansion of an article in the *Annals of Medical History* three years ago, and is brought out in the attractive style characteristic of the works published by Paul B. Hoeber. Crawford Williamson Long (1815-1878) was a country practitioner and did not publish his discovery until 1853, and in the meanwhile W. T. G. Morton, Horace Wells and C. T. Jackson brought their claims before the world. Thus arose a not very edifying dispute about priority. The matter, as Dr Puckard says in a brief foreword, may be summed up in the conclusion that Crawford Long first used ether to induce surgical anaesthesia and Morton first demonstrated this before a professional audience at the Massachusetts General Hospital, Boston, in October, 1846, when Warren Hayward and H. J. Bigelow operated upon a young man.

In a volume entitled the *Index Psychoanalyticus, 1890-1926*¹² Dr JOHN RICKMAN has collected other references to the subject of psychoanalysis since it was first originated. Such a compilation must be of the greatest service to all those who are interested in the study of modern psychology.

PREPARATIONS AND APPLIANCES

THE SCOTOPHOTOGRAPH

Mr. N. BISHOP HARMAN, F.R.C.S., recently showed to the Ophthalmological Society of the United Kingdom and to the Ophthalmological Section at the Cardiff Meeting of the British Medical Association an instrument designed by him to facilitate measuring the fields of vision where there is a central scotoma. The following is an abstract of his description of this instrument and its manner of use. I find taking is difficult where the macula of one eye is out of action. The device shown gets over most of these difficulties. A tube is bent at a right angle midway in its length and the two arms are so arranged as to give the seeing eye a false fixation spot which will correspond in position to the real one marked on the perimeter or scotometer. The figure shows the plan of the

instrument in reduced scale. E is the eyepiece. At the knuckle there is a double circle marked π for the reception of the handle. At the extreme right hand end of the tube is a plate in the centre of which is cut a diamond shaped aperture. At the knuckle of the bend of the tube is a large hole covered with a hinged lid α , fitted inside with a plane mirror. The patient holds the instrument before the eye which has fixation power. He sees the patch of light reflected from the mirror lid at the knuckle. The field of vision of the other eye and the scotoma are thereon mapped out. The instrument can be used for either eye. The scotograph (Mr Bishop Harman adds) is made by Messrs Weiss. It has been shown with the handle for holding in the hand of the patient, and this is the form I prefer, but the makers are prepared to fit it with a clasp arm to clip on to the upright of the perimeter.

SATURDAY, AUGUST 18TH, 1928

THE ORIGIN OF ENCEPHALITIS LETHARGICA

HISTORICAL speculations regarding encephalitis lethargica have, in recent years, given place to more practical considerations concerning the victims of this disease, but they have lately been revived by Dr A J Watson in an interesting paper on 'The origin of encephalitis lethargica,' contributed by him to the *China Medical Journal* for June, 1928. Dr Watson begins by asking what explanation can be given to the sudden appearance of this disease in the twentieth century. He is not disposed to accept the idea that we have been witnesses of the arrival of a new phase in the evolution of micro-organisms. On the other hand, he does not consider that medical researches have hitherto been able to trace any trustworthy historical antecedents of this epidemic infectious disease, and he doubts whether the disease—as we know it—could have existed in Europe and not have been recorded by some one among the many keen observers of the past two hundred years. But, as Dr Watson points out, Europe contains but a fraction of the world's inhabitants, and he suggests that the 'new' disease may have existed, and may still exist, as an endemic infection among the millions of the East, concerning whose ailments we are still largely in ignorance, and of which there are very few reliable historical records. Next, Dr Watson notes the significant fact that encephalitis lethargica appeared during the world war, when large numbers of Indians and Chinese served on various fronts, and where there was an unprecedented mingling of peoples from all five continents. Then, if ever, was the opportunity for the transference of disease from one country to another.

On the supposition that an endemic area or areas must exist somewhere, Dr Watson thinks that he has discovered such a focus in the Chinese province of Yunnanfu, to which, as a medical missionary, he, with his wife Dr Mary Watson, was posted for duty early in 1926. At the C.M.S. hospital in the town of Yunnanfu Dr Watson and his colleagues saw nineteen cases of post-encephalitis between February 28th and December, 1927, during this period 10,000 patients in all attended the hospital for various complaints. There are several interesting points about the series of encephalitis cases. All the patients except one seen in the acute stage, were suffering from characteristic Parkinsonism, and most of the patients gave a history of previous diplopia. All except two were males, and the majority were between the ages of 13 and 36 years, two were described as tribespeople, the others were Chinese. But there were other and more interesting circumstances of these cases, and some of these 'compelled' Dr Watson and his colleagues to consider the disease as endemic in the district. In the first place, the province of Yunnanfu, from which all the patients came, is a comparatively isolated part of China, where travelling is not easy,

and where, in normal times, the inhabitants do not mix with people outside their own district. All except three of the patients, who lived in the city of Yunnanfu, came from country districts and from separate isolated villages, while the majority asserted that they had never previously left their own neighbourhood. Next, Dr Watson lays stress on the length of time the symptoms had persisted in most of his patients, and particularly in the case of two, whose original attacks are stated to have occurred one in 1915 and the other in 1919, of the remainder, one had a history of seven years, one of six, one of five two of four, and the others three years or less. The evidence as to the dates of primary attacks rests on the testimony of the patients or their friends but Dr Watson thinks this is trustworthy, the first two patients, who were examined also by other medical men, never varied their answers on this point. Dr Watson makes the further observation that if, contrary to his belief, the disease originated in Europe and spread thence to China it would have behaved as it did on the Continent, in England, and in America, and shown itself in epidemic form on such virgin soil. But, so far as he knows, no case has occurred among the colony of 3,000 Cantonese in Yunnanfu, who are the travellers of the district, and Dr Watson himself met with no cases during the period January, 1924, to August, 1926, when he was stationed at Pakhoi, a treaty port in trade communication with Hong Kong. Moreover, foreign trained Chinese doctors long resident in the district have no knowledge of any epidemics of encephalitis having occurred in Yunnanfu.

Dr Watson's paper is extremely interesting. To have met for the first time in an isolated province of a country with which he was familiar no fewer than nineteen cases of chronic encephalitis within a period of eleven months is an event which in itself may well have set the observer thinking hard. The fact that it was during the world war that cases, or at any rate groups of cases, of the disease first came to light in Europe has, of course, long been appreciated, and it may be recalled also that it was among the subjects of the chief belligerent nations that cases of the disease first appeared. Dr Watson evidently considers it significant that in one of his patients the primary attack occurred at an early stage of the war—namely, in 1915—and apparently the inference is that there may have been other undiscovered cases occurring in China about or before that time. Among Western races it is true that the disease first attracted notice towards the end of the war, from 1917 onwards, but it may be noted that some reliable authorities in this country consider that before the war they were treating isolated cases of an obscure nature which in the light of subsequent experience, they now think may have been cases of encephalitis lethargica.

The great war certainly provided a unique opportunity for the escape and reactivation so to speak of an infection which up to the outbreak of hostilities may have been lying latent and comparatively harmless in some isolated community and there is nothing fantastic in Dr Watson's general hypothesis that it was from the East and from such a district as that of Yunnanfu, that the infection was carried by Asiatics, and by them distributed among the subjects of other races with whom they fought and mingled. There are, indeed, instances quoted by Hall¹ of isolated cases occurring among French and British troops in 1916. Speaking generally, however, there were no serious outbreaks of the disease among the European

¹ *Epidemic Encephalitis, 1924* p 7

armies while in the field, nor, later, was there any special incidence of the disease either among ex-service men or among their families. The sparse but widespread distribution of sporadic cases of encephalitis lethargica in this country did at one time suggest that infection was dotted about the country by returning soldiers, as was the case with malaria for a few years after the war, but the facts are against this explanation. It is not easy to explain, therefore, how exactly the sudden appearance of the disease can be correlated with the events of the war possibly, as with cerebro spinal fever, it was the military massing of individuals that raised the carrier rate to such a point that clinical cases began to appear and constitute epidemic outbreaks. But to appraise properly the merits of Dr Watson's hypothesis it would be necessary to investigate the facts concerning the movements and distribution of Indians and Chinese in the war areas, and to probe carefully the records concerning the occurrence of cases on those fronts where Asiatics and Europeans were in close contact. It is to be hoped, however that Dr Watson and his colleagues will continue their local researches with the view of learning as much as possible about the historical traditions and present day distribution of the disease in China. The lack of documentary evidence and the fact that in this disease the Western doctor can achieve no spectacular cures which will attract more cases to his clinic, undoubtedly make such researches particularly difficult. But this stimulating paper has certainly provided another instance of the good work done by medical missionaries, who, with the scantiest facilities, have yet not missed their peculiar opportunities for throwing light upon epidemiological matters in many obscure corners of the world.

PARATYPHOID FEVER IN THE LONDON AREA

TOWARDS the close of last month what is known technically as a 'burst' of paratyphoid fever occurred in London and several of the Home Counties, and cases continue to come to knowledge. Up to the end of last week about 160 cases had been reported as having occurred in London while others had also been reported at Epsom Sutton Carshalton Beddington, Wellington New Malden and Dorking in Surrey, at Northwood in Middlesex and at St Albans in Hertfordshire. The onset of illness appears in the bulk of the cases to have taken place round about the end of the third week in July and, allowing for the incubation period, the facts suggested that towards the end of the first week in July something had happened which led to a rather widespread diffusion of *Bacillus paratyphosus* B about that time.

Medical officers of the Ministry of Health, of the London County Council and of the local sanitary authorities in whose areas the cases occurred have been busily investigating the facts of the outbreak and these inquiries appear to have narrowed the channel of convection to the consumption of cream supplied by a large distributing firm to all the affected districts. Bursts of epidemic disease of this kind are usually associated with the consumption of some common article of food or drink which has become contaminated with the specific virus causing the disease. Water and milk perhaps the most common vehicles of diffusion in such cases appear to be ruled out in the present outbreak of paratyphoid fever in the London

area, but the evidence incriminating cream distributed about the end of the first week of July is, we understand, cumulative and convincing.

Necessarily, as in every epidemiological investigation conducted while the facts are still unfolding themselves, conclusions are tentative and subject to revision in the light of all the facts which later experience may disclose. But assuming it to be finally established that the present outbreak is due to contamination of cream distributed on a certain day or days early in July, what ground is this for the campaign upon which certain daily newspapers have embarked for revoking the Regulations of the Ministry of Health prohibiting the sophistication of food by so called preservatives? If cream is the medium of diffusion of the infective agent responsible for this outbreak it is because it has become grossly contaminated with the paratyphoid organisms. Would any sensible person, knowing this to have occurred, risk consuming such cream because it had had a 'harmless' modicum of boric acid added to it? The question need only be asked to show how misdirected is the exploitation of this outbreak in the interests of a reactionary pseudo hygienic propaganda. Already trade interests have secured the fortification of cream against such untoward infections by the employment of means far more efficacious than admixture with chemical reagents of the antiseptic order—namely, by pasteurization. But even efficient agents such as pasteurization fail upon occasion, as in the case of the present outbreak. Pasteurization may not be hygienically ideal, but properly controlled it is at least more efficient and less harmful than the process of further contaminating the foodstuff with injurious chemical substances which, under the conditions necessarily imposed, are germicidally inadequate to render innocuous foodstuffs contaminated by the organisms of infectious disease.

When we read in one of the newspapers that the absence of preservatives in perishable foods does tend to increase the risk of their becoming infected, and that the possibility of the epidemic of paratyphoid being due to the prevention of preservatives in food has caused the Ministry of Health to take action, we are indeed presented with a new kind of health propaganda based on etiological principles with which we must confess ourselves unfamiliar. This new group of deficiency diseases will be interesting to the hygienist of the future. The older hygienists will be content to continue to insist on the importance of preventing contamination of food stuffs, on the observance of strict cleanliness in their production, distribution, and storage, and, as a second line of defence, to rely positively on heat for the destruction of overlooked contamination and negatively on cold storage where perishable articles cannot be consumed in their fresh condition.

In the present outbreak of paratyphoid fever there has been a breakdown in this hygienic regime at some point so far undiscovered. There would be no additional security to the public against outbreaks of this character were a "minute quantity of boric acid" permitted to be added to cream as a preservative. It is not in the public interest that an outbreak of infectious disease calling for calm and experienced investigation should be made the subject of a news paper stunt and exploited to revive a practice which has been abolished in America and in regard to which, as the result of careful, prolonged and skilled inquiry official prohibition has tardily followed in this country.

PAY BEDS IN HOSPITALS

A SUMMARY of the report of the special Pay Beds Committee of the King Edward's Fund for London will be found at page 319. This report will command attention, while dealing with Greater London, it merits consideration by others than London citizens and hospital medical staffs, for changes in conditions in the metropolis will certainly have their reactions upon the country generally. The evidence obtained by the committee reveals the number of hospitals which have pay beds, and the great variety that exists in such provision. It is an indication of a widespread and new activity, boards of hospitals and medical staffs are trying out, each according to local conditions, schemes adapted to the needs of their clientele as they see them. Time is needed to show what direction the main line of advance will take, the committee suggests that there will be room for considerable variations at all times, for the circumstances of localities and population differ so widely. Of the need for an extended provision of pay beds it has no doubt, there are at present rather more than 1,000 beds, and the committee thinks that nearly 7,000 are needed. How many of these must be new beds they do not know, since the extent of the existing provision in nursing homes will not be revealed until the Nursing Homes (Registration) Act, 1927, becomes effective. That Act may reduce the number of beds in nursing homes, since the less efficient will probably close down where improvement is not feasible. The committee agrees that for the most part pay beds should be for an intermediate type of patient, it does not exclude the possibility of provision for the well-to-do, on the American model, but it thinks it would be difficult to graft that model on to the existing British practice. Pay beds are not new. The Florence Nightingale Hospital was founded in 1850, other pay bed hospitals have been established since and have done admirable work, but the greatest extension has been through additions to existing voluntary hospitals—a method which is less costly. These additions, however, bring with them their own difficulties in the matter of staffing. Should there be a "closed" staff limited to the existing members at the hospital or a larger staff amounting to free choice of doctor? It would appear that the committee inclines to the solution presented by the British Medical Association policy, that where the pay beds are an integral part of the hospital building a "closed" staff is generally necessary, but that where the provision is separate there should be an "open" staff. The committee concludes, however, that an extended provision must be paralleled by an extended association of all registered practitioners with the work of the hospitals, if only because the success of such ventures requires the goodwill of all practitioners. The fear is discounted that pay beds will militate against the continued popularity of the voluntary hospitals. The reverse is found to be the case, the popularity of the hospitals appears to be increased. It seems only natural that it should be so, for what is found desirable by the citizen who can pay for it will be appreciated by the citizen who cannot pay. The committee emphasizes the need for better accounting by the hospitals, with separate "costing" for the several departments, so that the real cost of pay beds may be known. Additions, they suggest, should be met from new money provided for the purpose, so that the cost shall not be a charge upon the general funds of the charity. For the most part the conclusions of the committee are in agreement with the recommendations of the hospital policy of the British Medical Association, but upon one point there is a sharp difference of opinion. The report states:

No patient in a pay bed should pay any fee to a physician or surgeon, whether a member of the medical staff or not, for treatment received in the hospital, unless the charges which that individual pays to the hospital

cover the whole cost to the hospital of his current maintenance." The British Medical Association policy reads: "This understanding for gratuitous service was mutual and reciprocal, and the general tendency now existing for the exaction of payment, however small, from the patient, necessarily modifies the original understanding." Where the board of a voluntary hospital received contributions from individuals in return for, or in anticipation of, treatment, the members of the visiting medical staffs should receive recognition of their services. "The thought in the minds of the members of the Pay Beds Committee would appear to be that so long as any part of the maintenance of a patient is provided by charity the service of the medical staff should be wholly a charity. Clearly there is no equity in this proposal, justice would be met by making the charitable contribution equal on both sides, and providing that the charity given by the staff should be proportional to the charity of the hospital benefactors. The suggestion of the committee is inconsistent, for the phrase "current maintenance" would appear to exclude overhead and capital charges, which would still be a provision of charity and yet allow of medical staff recognition. In the West London Hospital, when the late Mr. Dan Mason made the splendid benefaction which provided the pay bed wing, he promised to meet deficiencies on working on the scale of charges arranged, and agreed that the medical staff should receive recognition of their services as a matter of course. It would appear, therefore, that benefactors may have wider views than the members of the special committee. There is a more important reason for taking exception to the conclusion of the committee. Patients who now pay in part or whole as occupants of hospital beds—general or pay beds—are often those who were formerly attended in their own homes or in the lesser nursing homes, and for their treatment the attending practitioners—general and consultant (mostly the younger members of hospital staffs)—received fees adjusted to the circumstances of the patient. If more of these patients enter hospitals the ranks of the younger consultants will be sadly thinned. Steps to counter the deficiency of staffing would become imperative, and if, as has been done in some hospitals, this difficulty is met by appointing salaried resident assistant surgeons and physicians, a move will be made towards a stipendiary hospital staff which may have grave reactions upon the status of the voluntary hospitals.

RESEARCH AND ECONOMY

THE study of economy, in the abstract at least, is as common in political circles as the study of research work in the scientific sphere, and it is therefore not at all surprising that the Select Committee of the House of Commons on Estimates should have seen fit in 1926 to suggest that more attention should be paid to the co-ordination of Government research "with a view to economy and efficiency." In accordance with the usual procedure, as the suggestion was accepted by the Cabinet, a subcommittee of the Committee of Civil Research was appointed to consider the question, and its report¹ has now been published. Mr. W. G. A. Ormesby Gore, M.P., Under Secretary of State for the Colonies, was chairman of the subcommittee and his colleagues included Dr. W. D. Elliot, M.P., and Sir Walter Fletcher, secretary of the Medical Research Council, in addition to representatives of interested departments and of the financial "watch-dogs" of the Treasury. It may be noted at the outset that the subcommittee has not, apparently, found any general ground for the belief that there is much scope for "economy" in the present organization of State-aided or

¹ London: H.M. Stationery Office or through any bookseller. 1928. 2s. 6d. net.

State-controlled research, the report, therefore, is descriptive rather than critical. It is valuable, however, in that it gives an admirable survey of the existing system, with some interesting comments on its characteristic features. The influence of the State in relation to scientific research is, of course, the power of the purse, and the report therefore takes the financial basis of the system as its starting point. Much of the money given in the form of Government grants to the universities is employed in the promotion of research, while there are several organizations, established and maintained by the State, which are devoted to research of a more "utilitarian" type (to use the subcommittee's phrase) than that which proceeds in the academic sphere. Among these organizations there is the Medical Research Council. This body enjoys practical autonomy, it has full executive responsibility, complete administrative control of all work within its own scope, and is financed by the system of a grant-in-aid which allows it complete discretion as to the nature of its expenditure. It is an interesting comment on the relation between economy and research that this method has proved highly satisfactory, the scientific members of the Council, actuated by a desire to secure the maximum for research proper, have a direct interest in enforcing the utmost economy in other directions. The range of its activities is considerable, it assists investigators engaged on approved work at suitable institutions in diverse ways, conducts organized inquiries, maintains the National Institute for Medical Research with a permanent staff (this including a biological standards department), supports a department of experimental medicine and a national collection of type cultures, provides for the work of the Industrial Fatigue Research Board, and undertakes various other auxiliary works. The Council co-operates with the Ministry of Health, the Scottish Board of Health, and other Government departments, with the medical branches of the fighting services, and with other research organizations, notably those in connexion with industry. It is significant to note, in view of the suggestion which led to the initiation of this inquiry, that while there is no imposing effort at organized co-ordination the subcommittee found ample evidence that there is practically no "departmentalism" in the field of research. The Government agencies, the universities, medical schools, and technical institutions, the various learned, professional, and trade societies, and a multitude of private organizations and individuals are all, in the main contributing their quota to the sum of knowledge unguudgingly. There is, however, one limitation which should be remembered as applying to State aided research, particularly in connexion with industry, but to some degree also in other directions. State effort is confined, by its nature, to work which is primarily unremunerative. Here, as in other matters, the State undertakes that which does not offer the prospect of profit to private enterprise. Criticism of the results of research is therefore almost impossible on financial grounds, the yield cannot be reduced to a monetary value.

POST GRADUATION STUDY

ALTHOUGH it is almost a commonplace that medical education, at any rate of the more practical and useful kind, begins rather than ends with the acquisition of a degree or diploma, medical post-graduate study has not yet reached the degree of development which is obviously desirable, particularly in these days of rapid scientific progress. This is to some extent due to the fact that what medical practitioners need in this respect is difficult to formulate precisely and, therefore, hard to supply. Some recently qualified students contemplate training in specialties, others require opportunities for practical work—apart from house appointments—which may supplement their book know-

ledge. They have generally small financial resources, but ample time and freedom from domestic ties. On the other hand, a practitioner of several years' standing who wishes to keep abreast of the latest knowledge and methods can, as a rule, afford less time but more money. It is perhaps insufficiently recognized that these two classes of graduates need very different kinds of educational facilities. The results would probably be better if more careful consideration were given to this point by post-graduate training centres and by would-be students. A third group is that of intending specialists who wish to cultivate a limited field more thoroughly. At present those responsible for providing training facilities and for constructing programmes aim too often at satisfying all these groups simultaneously, with consequent disappointment. Moreover, in this country there is a relative lack of opportunity for practical work as contrasted with the case in certain Continental countries, where, for example, operative dexterity can be acquired under the personal supervision of distinguished surgeons. The question is largely one of finance, as is indicated by Dr W. D. Cutler, dean of the New York Post Graduate Medical School, in a report in the July issue of the *Bulletin of the Association of American Medical Colleges*. Those who are endeavouring at our leading medical hospitals and medical schools to improve the methods of medical education are to a large extent handicapped by having to work in old buildings designed for the conveyance of information verbally rather than for the development of dexterity. This contrasts sadly with such clinics as those of Vienna, which were built just before the war. The arrangements in that city enable patients to be wheeled on beds into the lecture theatres, special laboratories—apart from the main ones of the institution—are provided for students, and each building forms a complete unit, with full accommodation for radiological and other investigations and for various forms of treatment. Again, in Paris the tendency for certain hospitals to specialize for such general subjects as surgery, medicine, and gynaecology facilitates remarkably the post-graduate training of general practitioners, and such considerations must be borne in mind by those who are endeavouring to improve matters in Great Britain and to attract a larger number of students from our own and from other countries. One reason which leads some practitioners in this country to contemplate a course of study abroad is that it can be combined with a holiday for themselves and their families, and the language difficulty is not insuperable in some centres of medical education. For example, the American Medical Association of Vienna caters for practitioners from all English speaking countries, and arrangements are made month by month for special practical courses in all subjects in our language. But, whether taken at home or abroad, post-graduate instruction is becoming of more importance every year. The interest taken in this matter by the late Editor of the *British Medical Journal*, Sir Dawson Williams, is well known, it may be added that in the head office of the British Medical Association a considerable mass of information about post-graduate facilities at home and abroad is being accumulated for inquirers. Moreover, the value of the increasingly numerous clinical meetings of Branches and Divisions of the Association should not be overlooked. Progress in the science of healing will obviously become more rapid when general practitioners can be brought into closer practical touch with modern developments, and the present tendency towards internationalism might well be turned to account, not only in the interests of British medical men and women who wish to acquaint themselves with the practice of the chief medical centres on the Continent, but also of visitors from abroad, who would gladly come to our teaching institutions if the language and other difficulties could be diminished. The

facilities already existing in Great Britain are too little known, and even to-day it is possibly not superfluous to mention the work of the Fellowship of Medicine and Post-Graduate Medical Association in respect of London Announcements by the Fellowship appear regularly in our columns, and further information about courses and general clinical work can be obtained from 1, Wimpole Street, W 1.

THE CRIPPLES JOURNAL

THE July number of the *Cripples' Journal* contains the weighty announcement that with the October number it will become an international quarterly periodical managed by an advisory council of representative European surgeons under the chairmanship of Sir Robert Jones and under the editorship of Mr Frederick Watson, who has so ably tended it from its birth and through its infancy until now. We welcome this announcement, for it has for some time been evident, to our thinking, that if the magazine was to have the influence that it should have, it must divest itself of the local associations of its origin and become representative of a much larger number of those interested in cripples and of their views. The current number contains much that will appeal to workers among cripples, including an instructive article by the editor on "What is the Red Cross doing?" followed by one on "The Red Cross in the After-Care Clinics," by Commandant Sylvia Tower, who gives an interesting account of the work done by the Red Cross nurses in orthopaedic clinics, which last, indeed, could hardly exist without their help. Miss Margaret B Cross describes the organization known as the Junior Red Cross, a movement which was first officially recognized in Canada, and the objects of which are the inculcation of the laws of health and the rendering of help to sick and suffering children by their more prosperous brothers and sisters—in short, the observation of the precepts of practical Christianity. Other articles in this number deal with certain cripples' hospital schools and with infantile paralysis. Mr A Roever-Jones contributes a short but clear account of John Hunter, under the serial heading "Pioneers of Orthopaedics."

INTERNATIONAL COMMITTEE ON RHEUMATISM

It will be recalled that the International Committee on Rheumatism grew out of the International Society of Hydrology, and in view of the present campaign against rheumatism in this country the report for 1927 of the central advisory body is of special interest. In March, 1927, the Health Department of the League of Nations was approached, with the result that the question of co-operation is under discussion. The International Committee on Rheumatism has established a central bureau at Amsterdam, and an international library has been founded, with over 1,000 volumes at the present time. The work of the bureau in assisting in the periodical publication of lists of books, pamphlets, and articles on the rheumatic problem has been found most useful by the different national committees, and many communications on the social as well as on the medico-scientific aspect of the subject have been exchanged. The committee proposes to make a statistical study of rheumatism in all countries and for this purpose the scheme of the British Ministry of Health is to be used. The foundation of laboratories and the publication of an international journal devoted to the problems of rheumatism are also under consideration.

PAY BEDS IN LONDON HOSPITALS

REPORT OF THE KING EDWARD'S FUND COMMITTEE

ON July 21st (p. 120) we mentioned briefly the chief findings of the report of the special committee of King Edward's Hospital Fund for London on the provision of pay beds in voluntary hospitals, a further account follows of the data collected and of the conclusions reached. The committee held twenty-two meetings and examined forty witnesses, among whom was a deputation from the Hospitals Committee of the British Medical Association consisting of Messrs H S Souttar, W McAdam Eccles, N Bishop Hamman, and Dr G C Anderson, Deputy Medical Secretary.

A questionnaire was addressed to the several London hospitals to ascertain what provision of pay beds existed, how they were worked, and what schemes existed for the extension of such accommodation. The striking feature of the replies received was the great variation of the schemes in existence, scarcely two of them agreeing in essential details. In the opinion of the committee this does not indicate anything in the nature of chaos, but rather that the hospitals are feeling their way towards the best method of making such provision, and that instructive experiments are being conducted. There is general agreement as to the need for such pay beds. The development of expensive methods of treatment and diagnosis, which has become a commonplace feature of the work of the voluntary hospitals for the poor, has left the middle and professional classes unprovided for in this respect, for it is conceded that private nursing homes do not provide these forms of treatment. Further experience has revealed the fact that where such provision is made for these new classes of hospital patients there is no lack of demand, but rather an excess. It has also been shown that many of the patients who have hitherto been treated in the general wards are quite able and willing to meet the cost of pay beds.

The committee recognizes four types of patients those who cannot pay anything and whose treatment must be free, those who can pay for maintenance in the ordinary wards and yet receive free treatment, those who desire and will pay for the privacy of the private ward, contributing somewhat towards the cost of treatment, and those who can afford the full cost of nursing homes and medical fees. An endeavour was made to find a dividing line between the second and third type of patient. Replies indicate that the highest payment normally received from patients in the ordinary ward is about two guineas a week, the average being possibly as low as 15s even when the free patients are omitted. Income limits showed that the scale of the British Medical Association and that adopted by the Hospitals Saving Association of £4 a week for a bachelor, £5 for a married couple without children under 16, and £6 for those with children gave a fair indication. Many hospitals which have pay beds have income limits, these range from £300 to £800 a year, though there are a very few that make allowance for higher incomes by taking family conditions into account. It is estimated that of the 8,000,000 people of Greater London between 5 and 6 million fall into the type of free patients, 2½ million, or 600,000 families, into the middle or professional classes, and 25,000 are of the well-to-do type. Replies to the questionnaire were received from 150 hospitals, having 15,600 beds; eighty hospitals had pay beds accommodating in all 1,055 patients. Of these beds 164 were in hospitals with medical schools, 353 in other general hospitals with resident medical officers, 126 in hospitals without resident medical officers, 127 in hospitals for women, 28 in children's hospitals, and 125 in other special hospitals. In all 477 are situated within three miles of St Paul's, 429 between three and seven miles away, and the rest farther out; it is these distant hospitals which do not have resident medical officers. Beds are provided in single rooms, and there is every gradation up to wards accommodating as many as 24, with permanent or temporary screens. Privacy appears to be the chief desire of patients in these beds, but they may enjoy certain other advantages—more nurses (all fully trained), ampler diet or wider choice of food, better crockery and furniture—though some hospitals make no difference between the pay beds and the general wards.

We regret to announce the death, on August 12th, of Mr George Edward Wherry, MCh, FRCS, for many years university lecturer in surgery and consulting surgeon to Addenbrooke's Hospital, Cambridge. We hope to publish a memoir in our next issue.

Wide Variations in Charges

Pay beds are no new provision, the Florence Nightingale Hospital was founded in 1850. The greatest increase in the number of such beds, however, has occurred since 1920, and in the last eight years 465 have been added, while during the same period 1,600 new ordinary beds have been provided, in 1920 pay beds were 4 per cent of the total, now they are 7 per cent. Charges vary greatly, but about half the hospitals have rates of four to five guineas a week, a few go so low as two guineas, and still fewer as high as nine or ten guineas. The high-priced beds are at the teaching hospitals, the lowest at small hospitals on the outskirts of Greater London, which have no resident staffs. Charges are fixed by the estimated cost of the pay beds to the hospital and the means of the prospective patients. The first factor is not easy to ascertain, for most hospitals do not keep separate accounts of this department of their work; it is suggested that a complete system of costing would automatically disclose the real figures. The lines for such costing have been suggested by the King Edward Fund. Estimates of the capital expense of the beds are still harder to ascertain, but it is said that a complete pay bed hospital could be built and equipped for something less than £1,000 per bed, exclusive of the site. The total charge to the patient is of some interest. At the West London Hospital, where the parties to the treatment—doctor and patient—have the choice of making their own terms or leaving the assessment to a special committee, about 75 per cent of the patients are so assessed at a total inclusive cost, including the medical fee. The average cost works out at most hospitals at about three weeks' maintenance charge plus the medical fee, while the average medical fees paid range from merely nominal amounts of five guineas for an operation up to a third or, occasionally, even one-half of the usual fee. In seven hospitals no fees are allowed whatever the work done, though this does not preclude consultation fees before and after the stay in hospital.

Arrangements for Medical Attendance

Here again there is much variety in practice. In some of the large hospitals the treatment is confined to the normal staff of the hospital; in others any recognized consultant may attend his patient; elsewhere treatment is open to any registered practitioner, and the patient has free choice of doctor. The beds where the treatment is limited to the members of the staff of the hospital number 640, or just over one-half the total available, these being nearly all in the large hospitals. In two of the teaching hospitals—St Thomas's and Guy's—there are pay wards, and consultants on the staff of other teaching hospitals are permitted to undertake treatment of the patients in them, but it appears that very few take advantage of the facilities. The more distant the hospital is from the centre of London, the wider is the choice of doctor. Differences in practice, the committee finds, arise partly from circumstances and partly from policy, but it is held that, quite apart from any question of finance, the limitation of the medical staff causes the outside consultant and still more the general practitioner, to lose touch with his patient, and that the development of the pay bed system should afford increased opportunities for the ordinary medical practitioner to come into contact with the latest developments of work under hospital conditions, and should provide him with increased institutional facilities. The question of practicability is discussed, and the view expressed in the policy of the British Medical Association is cited, that whereas wards integral with the hospital may have to be counted as part of the hospital, there is no obstacle to complete freedom in separate paying blocks, which should be administered on the same lines as an ordinary nursing home.

The responsibility of the managers of the hospital is considered, and it is suggested that if questions of status arise concerning individual doctors (which does not often happen), they are settled by the medical authorities of the hospitals. Where treatment is open to general practitioners a wider definition is required, and the three criteria of the British Medical Association are cited. (It should be noted that the inclusion of these within the hospital

policy of the Association was rejected at the recent meeting of the Representative Body.)

The recommendation of the British Medical Association that, except in emergencies, patients should only be admitted on the recommendation of the attending practitioner is discussed, and there is a final statement that "the maintenance of relations with the general practitioner would obviously be most important to the success of any large extension of the pay bed system, if full use is to be made of the beds."

The Demand for Additional Pay Beds

Numerous witnesses testified to the existence of such a demand on a large scale. The most emphatic expressions come from the larger general hospitals, and where there have pay beds the waiting lists are evidence of the demand. Patients who cannot wait go elsewhere, and it is believed that the lists themselves represent only a fraction of the unsatisfied demand. The pressure does not always produce a high average of daily occupation. Some hospitals have a very high average, for example, Westminster with 13.7 out of 15, West London with 23 out of 26, and St Andrew's, Dollis Hill, with 53 on a nominal 52. Holiday times lower the averages, and patients cannot always come when the vacancy occurs, the allocation of beds between the sexes sometimes causes difficulty, for the male ward may be overfull and the female partly empty, or vice versa. In some hospitals the pay beds are filled by ordinary patients when there are vacancies. It is estimated that the total beds needed would, on the figures before the committee, approach 7,000, including all the beds at present in existence; this estimate includes also beds in nursing homes. The voluntary hospitals at present provide about 1,000 pay beds, while the number of beds in nursing homes is not known, but this information should be ascertained so soon as the Nursing Homes (Registration) Act, 1927, comes into effect.

The effect upon the general working of the voluntary hospitals of the provision of pay beds is discussed. The hospitals do not appear to have suffered in popularity from having extended the scope of their work in this direction, but rather the reverse. There is, moreover, no reason to suppose that the addition of pay beds will prevent or delay the addition of beds for ordinary patients. "If, therefore, it is within the sphere of the voluntary hospitals to supply the demand for pay beds as well as the demand for ordinary beds, if there are practical schemes for adding more pay beds, and if by so doing the hospitals are satisfied that they will increase their popularity and their resources, with resulting benefit to the whole of their work, there seems to be no good reason why they should not do so. There may also well be room for the development of a larger kind of nursing home on hospital lines, if it can be made to pay."

As regards any large extensions in the future, the committee thinks the ideal to be aimed at is that the capital cost of providing pay beds should in all cases be met out of funds specially provided for the purpose, or out of the proceeds of building appeals in which the proposal to provide pay beds has been specially mentioned.

On one point the report of the committee diverges from the recommendations of the hospital policy of the British Medical Association. This will be found in paragraph 128, which reads as follows:

It seems to us that if patients are provided with special pay bed accommodation at less than cost price they are essentially in the same position in relation to the voluntary system as patients in ordinary wards. Here again we do not recommend that the King's Fund should make a hard and fast rule which would condemn particular arrangements such as those which may for instance be in force in connexion with special charities for the assistance of middle-class patients of limited means. But as the general principle for any considerable development of the pay bed system we hold that no patient in a pay bed should pay any fee to a physician or surgeon whether a member of the medical staff or not for treatment received in the hospital unless the charges which that individual pays to the hospital cover the whole cost to the hospital of his current maintenance and of any special services he receives from the hospital.

The report later indicates the way out of the difficulty—by insurance schemes for paying patients. "Whatever views are adopted on these questions, it is clearly desirable that as many of the patients as possible should be enabled

to place themselves in such a position that they can pay the full cost of maintenance in a pay ward, and a medical fee as well." It thereupon proceeds to examine existing schemes such as those of the British Provident Association and the Norfolk and Norwich Hospital, but it is recognized that these are on a small scale, and experience is still lacking as to the working of such a scheme over so large an area as London, with its many hospitals.

Scotland.

Scottish General Board of Control

THE General Board of Control for Scotland has issued its fourteenth annual report dealing with the management of lunatics and the control of mental defectives. It is stated that the Royal Commission of 1857 estimated the number of persons of unsound mind in Scotland as 7,403, or about 1 insane person to 413 of the population. In the year under review the rate was 1 for every 264 of the population. The Board welcomes the establishment of observation wards conducted on hospital lines by various parish councils. In the case of the wards at Stobhill and Duke Street, Glasgow, 1,240 patients passed through them in one year, and of these 788 returned to their homes without the necessity for certification. These wards have to some extent served the purpose of the clinics which are so well known in foreign countries, where mild cases of nervous and mental breakdown seek skilled advice and receive special treatment. The report considers that it would be desirable if the lunacy grant which is given for improving the care of the certified lunatic were changed so that the Board at its discretion, might assist all mentally affected persons. It is pointed out that as a rule all nurses, either male or female have to qualify for the certificate of the Medical-Psychological Association, which can be obtained only after three years' experience of mental nursing and by passing an examination. Attention is drawn to the great extent to which male nurses have been replaced by female nurses in the past thirty years, and it is suggested that a prolonged and severe course of training and an examination for male nurses, equal to that which is undergone by female nurses, is desirable. The increasing extent to which occupational therapy is utilized is commented upon. The exhibition of work from the various institutions throughout Scotland, which took place at Bangour Asylum in July, demonstrated into what useful channels it is possible to direct the energies of patients who, before the introduction of this method of treatment were distinctive, degraded, and costly from the point of view of nursing. Attention is also drawn to the fact that some of the largest institutions have visiting physicians and surgeons from the neighbouring cities, who deal with and advise in cases affecting their specialties. At the beginning of the present year there were in Scotland 18,702 persons officially recognized as insane, including the inmates of training schools for imbecile children. Of these, 2,957 were maintained from private sources, 15,675 by parochial rates, and 70 at the expense of the State. The number of escapes from establishments during 1927 was 129, of whom 55 were brought back within twenty-four hours, while 26 were still absent on the expiry of twenty-eight days from the date of escape. The total expenditure of local authorities for the maintenance of pauper lunatics for the year ending May 15th, 1927, was £779,332. The average cost per head was £51 14s 2d per annum in asylums, and £44 19s 6d per annum in poorhouses. The expenditure for the maintenance of aided mental defectives was £130,627.

New Royal Infirmary Stirling

THE new buildings of the Stirling Royal Infirmary were opened on August 10th by His Royal Highness the Duke of York. Mr. James Thomson, D.L., president of the infirmary who presided and welcomed the Duke and Duchess of York, said that the Stirling Royal Infirmary had been founded fifty years ago, and in that time it had undergone various extensions, which, however, had finally proved insufficient. The directors had decided to build a new hospital for 126 beds with a maternity home of 20 beds

and the cost had finally worked out at £108,000. It was gratifying to know, however, that this large expenditure had been fully met, and the infirmary was to be opened free of debt, the endowment fund not having been touched and remaining at over £70,000. The Duke of York, who opened the main entrance to the infirmary building, said that it was a pleasure to help a cause which must appeal to every man and woman. The infirmary was worthy of its supporters and had great beauty of site and excellence of buildings. To have raised the sum of £108,000 was a magnificent achievement of which the directors might be proud. The new hospital has been erected on fifteen acres of ground to the south west of the town of Stirling, on the Wester Inchlands estate. It stands on an open plateau, beautifully wooded, and commands magnificent views of the surrounding country. The main building runs east and west, with a corridor 600 feet long, and the main wards open off the south side of this corridor. On the north side are placed the kitchen, operating theatres and out-patients' and other departments. The building is two stories high with four surgical wards, two medical wards, and one children's ward, each of sixteen beds, with additional small wards. At the extreme west end of the building is the maternity block containing two wards of eight beds each, with two single wards and one two bed ward, accommodating in all twenty patients. A sun room or day room is also provided in connexion with the maternity unit, facing southwards with French casement windows opening to the floor. The main buildings are designed in a form of Georgian architecture, and a special feature of the main front is the provision of large balconies at the end of each of the wards on to which the patients' beds can be wheeled through French windows. The sanitary towers are placed at the north end of the wards, thus leaving the south end completely free of obstruction to sunlight and air. The building is heated by low-pressure steam and provided with electric lifts for patients' beds.

Red Cross Work in Scotland

A camp of Scottish voluntary aid detachments was held recently at Craigmennie, Aboyne, and was inspected on August 3rd by Lieut. General Sir William Peyton, G.O.C. in Scotland. About two hundred V.A.D. members attended camp under the command of Miss Gardner, assistant county director for Dumbarton. A large number of Red Cross county directors and others were present at the inspection, including the Marquess and Marchioness of Aberdeen and Temair, and Dame Beryl Oliver, head of the V.A.D. department in London. A demonstration was given by V.A.D. members of the working of a casualty clearing station, and at its conclusion General Peyton congratulated the nurses on the excellence of their work. He said that he believed that it was not only the event of war that made it desirable that women should be trained as nurses, there were at present all sorts of emergencies—from aeroplane accidents to motor smashes—in which women could give assistance. The War Office was most sympathetic and appreciative towards the work of the Red Cross, and would do still more if it were not for the necessity of keeping the Army Estimates low. In the evening the V.A.D. nurses attended a ball given by Lord Aberdeen to celebrate his 81st birthday.

Ireland.

Obstetrics and Gynaecology in Dublin

THE August issue of the *Irish Journal of Medical Science*, which is the official journal of the Royal Academy of Medicine in Ireland, is devoted to obstetrical and gynaecological subjects. Three annual reports of Dublin maternity institutions during 1927 are published in it—namely, those of the Rotunda Hospital, the Coombe Hospital, and the National Maternity Hospital. We have already referred on two previous occasions (May 5th, p. 771, and July 14th, p. 70) to the interesting report of the Rotunda Hospital by the master, Dr. Bethel Solomons, the valuable statistics associated with it are now available for closer study. In the Coombe Hospital report for 1927 the master,

Dr Louis Cassidy, deals on similar statistical lines with the work of this institution. In comparison with the Robunda report it is worth noting that, at the Coombe Hospital, the morbidity was reckoned according to two standards—namely, that of the British Medical Association, in which a case is considered morbid if the temperature reaches 100°F on two occasions between the second and eighth days of the puerperium, and Tweedy's standard, which defines morbidity as the appearance of a temperature of 99°F on three consecutive readings after the first twenty-four hours. According to the former standard the percentage of morbidity during the year was 5.0, whereas by Tweedy's method of recording it was 7.2. The morbidity figures in the Coombe Hospital for the year under review compare favourably with those of the previous year. Dr Cassidy regrets the absence of a dental department, and mentions the gratifying increase in the activity of the ante natal department, which has now been three years in existence. The clinical report of the National Maternity Hospital is shorter than those of the other two institutions. The master, Dr P. T. McArdle, reports a morbidity rate of 3.4 per cent, using the standard suggested by the British Medical Association. He comments briefly on the treatment of various emergencies, and records his approval of the use of axis-traction and Kielland's forceps. In addition to these hospital reports, this month's *Irish Journal of Medical Science* contains clinical notes by Dr Cassidy on eleven cases of vesico-vaginal fistulae occurring during labour, and the report of a case of double uterus and vagina, by Dr A. H. Davidson. Abstracts of obstetrical and gynaecological articles and reviews of new books on these subjects are other features of an issue which will interest obstetricians and gynaecologists generally.

The Down County Mental Hospital

In the fifty-eighth annual report of the Down County Mental Hospital, Downpatrick, the resident medical superintendent, Dr M. J. Nolan, comments on the importance of providing for suitable male mental patients facilities for farm work, since very many who enter this institution come from the agricultural classes. He considers, moreover, that no other form of occupation would take its place as a therapeutic agency, and that without it there would be fewer clinical recoveries and a general impairment of physical health. An outbreak of colitis in the institution involving eleven patients was traced to an outside source, and the discovery of the carrier resulted in the prompt arrest of what would otherwise probably have proved to be an epidemic, with possibly endemic sequelae. Dr Nolan emphasizes also the importance of the thorough investigation of each individual case of mental disorder; he adds that although patients in the more advanced stages are, for the most part, outside the scope of psycho-analysis, yet many have responded readily to sympathetic investigation and co-operation in the readjustment of their attitude towards the existing home and family conditions. The report contains numerous illustrations and statistical tables.

Typhoid Fever in County Galway

An outbreak of typhoid fever is reported from Lettermore, Connemara, and ten patients have been removed to the fever wing of the Galway Central Hospital. Dr Sterling Berry, medical inspector of the Local Government and Public Health Department, with Dr Tubridy, medical officer of the district, are investigating the cause of the outbreak. At a meeting of the Galway County Health Board it was agreed that Dr Tubridy should be given freedom to order the destruction of any articles which he feared might be infected, and it was suggested that the local relieving officer should be given a free hand in dispensing relief. A resolution was passed calling on the Government to give a special grant to the people of the area, and also asking that the recommendations of the Caclteacht Commission be carried out.

Scarcity of Nurses in County Carlow

No nurses having applied for the vacancies, recently advertised, in the hospitals of county Carlow, Dr Clinch, medical inspector of the Public Health Department, attended a meeting of the Health Board when this matter

was under consideration. It was stated at the meeting that the salary offered was £65 per annum, with rations (or their equivalent in money), apartments, fuel, and light in each case, and that the lack of applicants was due to a combination organized by the Nurses' Association which has been recently pointing out the inadequacy of the salaries offered by health boards in Ireland. The Board ultimately decided to combine the salary and allowances, and to allow all head nurses £100 per annum, and assistant nurses £80, with apartments, fuel, and light in each case.

Correspondence.

SPA TREATMENT

SIR,—The question, What is a spa? seems to be a little in doubt. Thus, the definition of "spa treatment" proposed at the Representative Meeting of the British Medical Association at Cardiff (*Supplement*, August 4th, p. 75)—"treatment at a place possessing a supply of natural mineral waters of reputed therapeutic value" (with buildings, apparatus, and trained personnel for work in bath-houses and other physico-therapeutic departments)—could not be accepted without further consideration. Some representatives from the coast objected to the word *mineral*, and would prefer to link in one definition the special treatment provided at the seaside with that provided at the spa. (It may be admitted that the word *mineral* is not now a very happy one as applied to medicinal springs, since many of these are less mineralized than ordinary town's water, and, moreover, the word has been captured by the table water industry.)

The same doubt or misapprehension about "spas" is evident in occasional public announcements. At the recent annual Foresters' Court, for example, the Chief Ranger expressed satisfaction at the project to make "spa treatment" available in London.

What are the facts? Historically, many of the great European health resorts have been named after their waters or baths—such as Aix, Acqui, Aachen, Bath, Carlsbad, Salsomaggiore, and Wildbad. In French the prefix *Bagnère*, or the suffix *-les Bains*, is often applied to the *stations hydro-minérales*, and in German-speaking countries the names *quellen* and *baden* are usual. Only in England have places of waters received the general designation "spa," annexing the name of the Belgian resort made famous by Peter the Great. Secondly, it is to be remembered that as a result of the modern study of physical remedies many necessary methods of treatment have been introduced at the spas, and have been so extensively used in England as sometimes to overshadow the use of waters.

Thus present-day treatment at spas includes two things: (1) the internal and external use of medicinal waters which cannot be obtained elsewhere, (2) other kinds of baths and physical methods of treatment—radiant, electrical, mechanical, etc.—which can be obtained elsewhere.

As regards the sea-coast places, the special treatment provided (modern thalassotherapy) includes exposure to the marine climate (heliotherapy, aerotherapy) with the use of sea water and seaweed and the usual necessary physical methods. These are all variously adapted at the different localities, like Torquay and Margate in Laglan, Arrecion and Bercy-sur-Mer, and Wyke on the North Sea. The marine resorts for children and elderly people on the coasts of England form an outer ring of health centres, which is assuredly not less important than the inland group, but the specific treatment they offer is climatic and marine.

Lastly the city clinic, to which the president of the Foresters referred, should have for its chief function to make the physical remedies which can be everywhere obtained conveniently accessible near the homes of the people.

It would surely be well if the spa, the marine health resort, and the physical clinic should each develop along its own special lines. To apply a name which is attached

to medicinal waters either to the coast resort or the clinic would be inappropriate and misleading.—I am, etc.,

11 LORTSLEY Lox

ETHYL PETROL

Sir,—The glaring advertisement "Ethyl is safe" is the sequel to the interim report of the Departmental Committee. Yet the Committee did not say that "ethyl is safe" it did say that it was not proved that ethyl is not safe with certain precautions, and it awaits further evidence. The blare of the commercial trumpet has drowned out the still small voice of the scientific Committee.

I agree with Dr. F. C. Ives (*British Medical Journal*, August 4th p 222) that "organized medical opinion is the last ditch in our defence against invasion by this diluted poison" but I do not agree with him that the British Medical Association should be saddled with the collision and scrutiny of evidence in respect of this stuff. The Association has plenty on its hands at the present time, but the medical profession by reason of its experience and position in the community has a special responsibility in this matter, and its members will have to consider whether, in view of that responsibility they are justified in using ethyl petrol and whether, if they are asked they would advise the public to use it.

There is no necessity to be alarmists or to rouse unnecessary fears. Ethyl petrol has a place in the world of the internal combustion engine for tests, races, and stunts but I think that the general opinion of the profession will be against it for extensive public use. Perhaps I should add that I have no interest, financial or other, in any of the oil companies that do not sell ethyl petrol.—I am, etc.,

Warrington Aug 10th

J S MASON

THE GUILLOTINE AND ETHYL CHLORIDE

Sir,—I submit that ethyl chloride is an unsuitable anaesthetic to employ for the operation of enucleation of tonsils. The most important step in the procedure is to prevent all unnecessary haemorrhage, as in other operations, using artery forceps if any particular bleeding point is troublesome. Although the bleeding at the time of operation is often considerable, if measures are not employed to prevent it the oozing which ensues during the next two or three hours will often far exceed this, and if allowed to continue, end in death. I will quote from Dan McKenzie (*Diseases of the Throat, Nose and Ear*) "Before returning the patient to bed make sure that the bleeding is stopped." Ethyl chloride does not allow time for this. Personally I prefer chloroform, and have it administered.—I am, etc.,

Liverpool Aug 13th.

E MALCOLM STOCKDALE

Sir,—There have been many contributions on this subject since the article of Mr Sandiford and Dr Clayton appeared in the *Journal* of July 28th. In a detailed account such as theirs it seems a pity that, while minute points of the part played by a porter are considered, examination of the tonsils after operation is omitted this important feature has not been mentioned in subsequent correspondence. This examination should be made in every case. The obvious rejoinder is "What can be learned?" and "What can be done if it is not complete?" The answer to both depends upon the anaesthetic used. With the closed (ethyl chloride) method one can only learn if both tonsils are complete, and whether the capsule has been "button-holed," the former indicating faulty technique, the latter a guillotine insufficiently blunt. Employing the open ethyl chloride and ether sequence, apart from the fact that there is far less likelihood of "missing a lower pole" should this contingency arise the patient can easily have the remaining portion dissected out, as in adult tonsillectomy, using a Shipway apparatus.

Another omission (I take it that it is an omission, since no mention is made of the practice) is the examination of the patients by a competent person before they are allowed to go home. Surely this is quite the most essential

part of the post-operative treatment. I have had to examine children two hours after tonsillectomy who have had closed ethyl chloride. With them it was practically impossible to get a view of the throat, much less remove any adenoid tags, which are quite frequent with even the most skilled surgeons. The adenotome may be recommended as the solution of this problem, but the septum can never be felt with this instrument, and it is consequently not so efficient as the eurette, whereas after the open ethyl chloride and ether anaesthesia the children are far more tractable, invariably in a better condition to return home, and (more important still) the possibility of adenoid tags persisting is reduced to a minimum, since they can be removed at the time of operation.

I would not, in my present position, have ventured to write this letter had it not appeared to me that two extremely important items in the operation have been totally disregarded. *Actum lente* is the ideal motto for a tonsil clinic.—I am, etc.,

ROUS TUMOURS

Sir,—In an editorial in your issue of July 28th you speak in terms of high commendation of Dr Murphy's views regarding the significance of specificity in Rous tumours. In the same issue you give a review of my book, *On Rous, Leucotic, and Allied Tumours in the Fowl*. It has escaped the notice of your reviewer that the above subject is discussed in full in all its implications and significances in Chapters VIII and IX of my book completed in June, 1927, and published in January, 1928.

Other points of possibly equal importance discussed in the book have not been remarked by your reviewer. Three only need be referred to. In the first place, Carrall's solid work on the etiology of Rous and allied tumours has, for the first time as far as I know, been given due recognition in the second place, it is pointed out that Gyo's work and the work of those (pro- and anti-) who have repeated his experiments is the subject of a basic fallacy (vide top of p 85) which, as far as I am aware, has not been stressed before. While, thirdly, the question of mesenchymatous or sarcomatous tumours (including leucotic and Rous tumours), being in reality diseases of a system—the reticulo-endothelial system—with consequent effect on the exact meaning of the term "metastases," is the burden of several chapters.—I am, etc.,

Aberdeen Aug 10th

J P MCGOWAN

AN UNUSUAL CAUSE OF PAIN AND HAEMATURIA

Sir,—I noticed with interest Mr Frank Harvey's report (July 21st, p 101) on an unusual cause of pain and haematuria, and think that mention of this somewhat similar case may prove interesting.

On August 3rd 1927 I had to perform an operation for a large irreducible inguinal hernia in a patient aged 74. The hernia was of old standing and the bladder was involved. In separating the adhesions the bladder was nicked making a small hole of only about 1/4 inch in length. This was immediately sutured with silk the operation was completed and the wound closed.

The patient made an uninterrupted recovery healing by first intention and was discharged on the eighteenth day. Three weeks after his discharge he complained of difficulty of micturition—only in the upright position. Lying in bed he could make a satisfactory stream but when he was upright the urine commenced as a good stream to stop suddenly with severe pain. The urine contained no blood but large amounts of urates and phosphates and a few pus cells.

The case was treated by daily bladder wash-outs with weak permanganate of potash and the urine very soon became much clearer. About eight days after this to my surprise the patient told me he had something to show me. He produced a pencil shaped calculus chiefly phosphate and about 1 1/2 inches long, which he had passed that morning. The calculus was the silk suture from the bladder surrounded by phosphates. He has had no more trouble with micturition since and is quite well.

The case is interesting because of the comparatively short space of time in which the suture was extruded.—I am, etc.,

EDWARD C ELLIS, M B, Ch B, D P H

Cockermouth July 23rd

THE CURSE OF NOISE

SIR,—I should like to support Dr Hilliard's suggestion (August 11th, p 276) that the Council of the British Medical Association should promote a bill in Parliament with the object of preventing a good deal of the unnecessary noise of which so many complain. One has only to read the letters which have recently appeared in the *Times* to realize how necessary it is that some action should be speedily taken. It would appear that no body of men is better qualified to draft such a bill or more likely to carry it to a successful issue. I feel sure that the attempt would be greatly appreciated by the public and would add to the influence of the Association.—I am, etc.,

Oxford Aug 14th

WM COLLIER

PAYING CENTRES FOR INFANT HYGIENE

SIR,—Your report of the Annual Representative Meeting of the British Medical Association at Cardiff states that the Representative Body reversed, by amendment, the Council's approval of the principle of paying centres for infant hygiene. In the discussion allusion was made to such a centre in Chelsea—presumably the Babies' Club, 35, Danvers Street. May I, as its honorary secretary, submit a few points which do not seem to have received due consideration by the speakers at Cardiff?

From references made to the State-aided infant welfare centres, the majority of the speakers seemed to be agreed that this work has proved a valuable educational force. Some went so far as to admit that the clinics provide general practitioners with work which would not otherwise have come their way. There seemed to be little appreciation, however, that the infant welfare movement, through its clinics, doctors, and especially its health visitors, has created a type of work which has never been undertaken before. Its success throughout the country shows how great was the need, and suggests that the lines on which it has developed have been right.

The middle-class mother has now begun to demand a similar regular medical supervision of her infants, as a preventive measure against disease and delicacy. In many instances she cannot get this from her family doctor, not always because he has not the specialized knowledge for this branch of preventive medicine, but because he cannot organize his work to afford time for the regular supervision of many healthy babies, nor can she afford the money for the necessarily frequent consultations. As a result, some such mothers have begun to attend State-aided welfare centres, others rely on advice of doubtful authority, such as is found in magazine articles or obtained from correspondence bureaux. Others, again, seek help from the nurse who attended them at their confinement, who in many cases was the chief arbiter of their baby's welfare during the first few weeks of life, but whose experience does not necessarily extend much beyond that period. Where lectures are used as a means of education (the method endorsed by the Association's amendment) the mother has to make selections from the knowledge thus gleaned with no one to advise her whether or not it applies to her own child.

In the Babies' Club an honourable attempt has been made to meet the mother's needs on the one hand, and to safeguard the general practitioner on the other. Advice is paid for at a proper rate, the mother may not join unless her family doctor's permission has been obtained, the medical officer of the club may not visit the baby in its home unless at the family doctor's request. While no completely acceptable definition can be given of "sickness" and "treatment," a conscientious attempt is made to exclude sick children, and to confine the advice given to points of management, feeding and hygiene. Profiting by the example of existing welfare centres, advice given by the medical officer of the club is followed up by home visits paid by an experienced health visitor. A very close insight is thus gained into the home conditions, which provides a sufficient answer to the formidable objection raised in the Cardiff discussion that the physician at the clinic must be ignorant of many of the most important factors in the child's life.

We appreciate the feeling of the Association that the trend of such movements is a matter of close concern to the general practitioner, but this development of the infant welfare movement will inevitably continue. Would it not be well to suspend judgement upon an experiment conscientiously planned to further the interests both of the profession and of the public?—I am, etc.,

London Aug 14th

PAMELA HONSLFY ROBINSON

HOSPITAL PATIENTS AND DOCTORS' LETTERS

SIR,—I should like to endorse what was said by Dr Ritchie in the *Journal* of August 4th (p 223). I find the same thing happening here in the Manchester hospitals. When I was a student at Glasgow it was customary for the staff at the hospitals there to refuse to see panel patients without a letter from their doctor. I think this is only just.

This is a matter which ought to be taken up by general practitioners as a whole, as it has been the cause of annoyance for some considerable time.—I am, etc.,

Broughton Manchester Aug 6th.

E HENDERSON

Obituary

DR CHRISTOPHER CHILDS, who died at West Looe, Cornwall, on August 6th, in his 82nd year, was formerly well known by reason of his interest in public health problems. He was born at Liskeard, and at Uppingham School was distinguished as an athlete. He received his medical education at Oxford, St George's Hospital, and the University of Bonn, he obtained the diploma L.R.C.P. in 1875, graduated M.B. Oxon three years later, and proceeded M.D. in 1887, having been admitted a member of the Royal College of Surgeons in 1879. In 1895 he obtained the Diplomas in Public Health of the English Conjoint Board and of the University of Cambridge. After holding the post of house-physician at St George's Hospital he returned to Uppingham as science master and medical officer, under Dr Thring, and took part in the temporary migration of the school to Borth, in Wales, during the outbreak of enteric fever at Uppingham. He then practised for some time in London, acting also as a lecturer at University College, and later went to Weymouth, where he was surgeon to the Weymouth and Dorset County Royal Eye Infirmary and physician to the Weymouth Royal Hospital. Throughout his active professional life he found time for the study of preventive medicine and epidemiology, and was one of the pioneers in the treatment of dysentery at the time of the South African war. He was the author of a number of contributions on epidemiology and water pollution to medical publications. Dr Childs was a Fellow, and had formerly been a member of the council, of the Royal Sanitary Institute. He was a member of the British Medical Association for over fifty years, and acted for a prolonged period as honorary secretary of the committee set up by the Annual Meeting at Bournemouth in 1891, which investigated the clinical evidence with regard to anaesthetics. Between that year and 1900, when the committee was merged into the Special Chloroform Committee, he devoted himself yearly to the classification and analysis of the thousands of returns submitted. On his retirement from practice a good many years ago he returned to his native county of Cornwall, where he took an active part in the social and political life of West Looe, identifying himself particularly with the local Conservative organization, the Boy Scout movement, and the Cornish fishing industry. He was a Knight of Grace of the Order of St John of Jerusalem. Dr Childs is mourned by his only son, his wife having died several years ago.

DR HERWOOD SMITH, who died at Chichester on July 21st, was well known in London during his active life as a gynaecologist, and in his later years, in retirement at Chichester, he participated in professional affairs on the scientific side. Born in 1837, he received his education at the University of Oxford, graduating in arts in

1861, and afterwards continuing his professional studies at St George's Hospital, London. In 1865 he obtained the diploma M.R.C.P., and graduated M.B. Oxon., proceeding M.D. six years later. He was for a time house-physician at St George's and later was appointed physician accoucheur and physician for diseases of women and children at St George's and St James's Dispensary. Subsequently he became senior physician to the Hospital for Women, Soho Square, and to the British Lying-in Hospital, and was for a period civil medical officer to the Chichester Military Hospital. Dr Smith was among those associated with the British Gynaecological Society in its early days, this body was subsequently merged in the Royal Society of Medicine, of which he was a Fellow. He was also an honorary corresponding Fellow of the Gynaecological Society of Boston, Massachusetts a vice president of the Society for the Study of Inebriety, and a member of the British Medical Association and of the Brighton and Sussex Medico-Chirurgical Society. His contributions to medical periodicals were numerous, and he was the author of *Practical Gynaecology* & *Handbook of Diseases of Women*. Two of his sons are members of the medical profession.

Mr FREDERIC DURHAM, who died on July 16th at the advanced age of 87, was a native of Northampton and received his medical education at Guy's Hospital, in which his brother, the late Arthur Edward Durham, occupied a place of distinction. Frederic Durham obtained the diploma M.R.C.S. in 1869, graduated M.B. Lond. in 1871, and was admitted a Fellow of the Royal College of Surgeons a year later. He occupied a succession of minor appointments at Guy's Hospital and ultimately was appointed surgical registrar. During his tenure of this office he developed a keen interest in pathological histology, a subject to which he gave much time and attention in later years. He was for some years surgeon, and later consulting surgeon, to the North-West London Hospital, but devoted himself very largely to assisting his brother in his work. He was a Fellow of the Royal Society of Medicine and of the Medical Society of London, and was greatly interested in the work of the Royal Medical Benevolent Fund, being a member of the committee of management until his death. In the old-established "Our Club" of Guy's men he was well known, and for some thirty years he was a familiar figure at the Bath Club, where he made his home, although suffering increasingly from osteoarthritis.

The British Medical Association has lately lost a valued servant by the death of Mr TREVER LAPWORTH, who had been Head Printer of this *Journal* since the beginning of 1911, and had spent the whole of his working life (some forty-four years) in the service of the Editorial Department. All who came into personal contact with Mr Lapworth were impressed with his extreme conscientiousness and his devotion to the welfare of the *British Medical Journal*. He was a loyal and most obliging fellow worker, who grudged no time or trouble in carrying out the responsible and exacting duties that fell to his lot week by week and year by year. Although his health and strength had been gradually failing for several years past he remained at work in the Printing Department until within a week of his death on August 10th. Mr Lapworth was in his sixtieth year and unmarried. The funeral, at Finchley on August 14th, was attended by the Editor of the *Journal* and other members of the headquarters staff of the Association who wished to pay a last tribute to their old friend and faithful colleague. Mr F. Martin of the *Lancet* was also present on behalf of the printing staff of our contemporary.

The following well-known foreign medical men have recently died: Inspector General Jacon, formerly director of the Val-de-Grace Military Hospital, Paris, and Commander of the Legion of Honour, Dr LÉON DUFOUT, of Tëcamp, the founder in 1894 of the first "Goutte de Lait," and Professor E. BOSTROM, a Giessen pathologist, aged 76.

Universities and Colleges

UNIVERSITY OF OXFORD

The Theodore Williams scholarship in physiology for 1928-29 has been awarded by the Board of Management, on the recommendation of the Waynflete Professor of Physiology, to R. A. Beaver of New College.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIO, TRINITY COLLEGE

The following appointments have been made:—Lecturer in Biochemistry William Fearon Sc.D. Lecturer in Biophysics James Bell, Sc.D. Lecturer in Applied Anatomy Arthur Chance M.D., M.Ch. Lecturer in Sanitary Construction and Planning Alfred D. Delap, B.A. Lecturer in Chemistry and Public Health W. O. Ramsdon M.A. University Professor of Chemistry Emil A. Werner, M.A. Sc.D.

The annual post graduate course in mediolue surgery, and allied subjects will be held this year from September 17th to October 6th. Particulars can be obtained on application to Professor A. T. Dixon, Deane Faculty of Physio.

The Services

TERRITORIAL DECORATION

The King has conferred the Territorial Decoration upon the following officers of the R.A.M.C. (T.A.) Majors R. I. Dacre, A. Young (ret.) and W. T. Briscoe.

ROYAL ARMY MEDICAL COLLEGE

The following prizes have been awarded at the conclusion of the summer course for houteants on probation Royal Army Medical Corps and Indian Medical Service Herbert Prize (about £20) highest aggregate marks Lieutenant F. McL. Richardson R.A.M.C. 1st Montefiore Prize (£20 and bronze medal) military surgery Lieutenant A. McMillan R.A.M.C. (2nd) Lieutenant S. S. Bhatnagar I.V.S. Parkes Memorial (medal and £5) hygiene Lieutenant F. McL. Richardson R.A.M.C. Ronald Martin (medal and £5), tropical medicine Lieutenant F. McL. Richardson R.A.M.C. Tulloch Memorial (silver medal) pathology by R.A.M.C. officer Lieutenant G. T. L. Archer Fayer Memorial (bronze medal) pathology by I.M.S. officer Lieutenant C. J. F. Cropper De Chaumont Prize second highest marks in hygiene, Lieutenant S. R. M. Mackay R.A.M.C.

Medical News.

The old students dinner of St Thomas's Hospital Medical School will take place on Friday, October 25th, at St Thomas's House, Lambeth Palace Road, when Mr Edwin Francis White, F.R.C.S., will take the chair.

The Fellowship of Medicine and Post Graduate Medical Association announces that a fortnight's all day course begins on Monday, August 27th, at the Queen Mary's Hospital, Stratford, E. In general medicine surgery, and the specialties. From September 11th to October 5th, on Tuesdays and Saturdays each week there will be lecture demonstrations in psychological medicine at the Bethlem Royal Hospital at 11 a.m. Four courses will be given from September 17th to 29th one being an intensive all day course in diseases of children by the staff at the Queen's Hospital, Hackney Road, where luncheon and tea will be provided by the hospital authorities. In the same period afternoon lecture demonstrations in ophthalmology will be given by the honorary staff at the Royal Eye Hospital, and an all day course in orthopaedics by the staff at the Royal National Orthopaedic Hospital. The fourth course undertaken by the staff of the Westminster Hospital, consists of instruction in medicine surgery, and the specialties. From September 25th to October 17th a series of lecture demonstrations in electro-therapy will be given at the Royal Free Hospital. Copies of syllabuses and information regarding the general course may be obtained from the secretary of the Fellowship 1, Wimpole Street, W.1.

The Sir Charles Hastings Lecture by Sir George Newman on "The foundations of national health" delivered at the British Medical Association House on March 21st has with the Association's consent been published in pamphlet form by H.M. Stationery Office (price 3d net). The lecture was printed in full in the *Supplement* to our issue of March 24th (p. 93).

The Royal Commission on Local Government, now engaged upon the second part of the inquiry entrusted to it of considering the relations between the various existing local authorities, has issued Part XI of its minutes of evidence (obtainable from H.M. Stationery Office or through any book seller, price 6s net). This contains evidence given on behalf of the Association of Municipal Corporations the Urban District Councils Association, the Westmorland County Council, and by Mr E. D. Shino, formerly Lord Mayor of Manchester.

THE Water Pollution Research Board of the Department of Scientific and Industrial Research has issued a summary of current literature relating to water supplies, sewage, trade waste waters, river pollution, and other related subjects. This summary has been placed in the Library of the Association, where it will be available for the use of members.

A SUBCOMMITTEE appointed by the Heart Committee of the New York Tuberculosis and Health Association has been investigating the criteria of the diagnosis and classification of heart disease, and its report—which takes the form of a textbook—will shortly be published by Messrs Paul B Hoeber, Inc., of New York. It comprises a uniform nomenclature and diagnostic criteria.

IN connexion with the sixth international congress for combating tuberculosis, to be held at Rome in September, arrangements have been made for visits from September 20th to the 24th to various tuberculosis and social hygiene institutions in Naples and the neighbouring towns. A descriptive book is being prepared for those attending the congress, who are also invited to the opening ceremony of two new pavilions for tuberculous patients in the Ospedale Provinciale Psichiatrico, Naples, and to other functions. For information about lodgings and the journey application should be made to the Compagnia Italiana Turista (CIT), Piazza Trieste 6 Trento, 45, Naples.

A POST GRADUATE course on cancer organized by Dr Gussset, director of the anti cancer centre of Strasbourg, will be held at the Strasbourg faculty of medicine from October 16th to 31st, when lectures and demonstrations on cancer will be given in the various departments of the faculty. The fee is 300 francs. Further information can be obtained from Dr Gussset, Hôpital Civil, Strasbourg.

SIR C J MARTIN, director of the Lister Institute, has been appointed by the Minister of Agriculture and Fisheries to be chairman of the departmental committee which will report on the reconstruction of the Royal Veterinary College with reference to the cost, the accommodation to be provided, the site of a new building, and arrangements to be made in respect of the Animal Pathology Research Institute now situated at the college. The other members of the committee are Dr O Charnock Bradley, Sir Merrick Barrall, Mr H E Dale, Sir Walter Fletcher, Mr J R Jackson, Sir E Cooper Perry, Major General H T Sawyer, and Lieut Colonel Sir Archibald Waigall. The secretary of this committee is Mr V E Wilkins of the Ministry of Agriculture and Fisheries.

DR. MARGARET E. McFILL writes from Belfast: I can speak only for Manchuria, where I have been a medical missionary for twenty seven and a half years. I agree with the Chinese informants that it is not true that patients pay retaining fees to their doctors which are discontinued during illness. Chinese "doctors" often guarantee "cures" and extract money from patients in advance. The "cures" are not always satisfactory. I cannot speak with authority for other parts of China, but do not think it likely that there is much truth in the oft-repeated story.

MATERNITY WORK IN RUSSIA

DR T. ENGEL (Birmingham) asks how he may obtain a copy or translation of the rules for maternity cases in Russia. He particularly desires information about ante natal work.

INCOME TAX

Wife's Medical Earnings

"S. D. T." is married and resides with her husband. Since November 1926, she has had a plate up at their residence, but so far there has been no financial return from patients. What should be deducted in her husband's return of their total joint income in respect of expenses?

* * * Apparently there has been no net cash income yet but presumably fees are or will be due for professional services so that on the basis of "hookings"—appropriate to a new practice—there would be no real loss. What expenses can be deducted in arriving at the book profit or the loss if there should be one, must depend so much on the precise facts that guidance is difficult. A obergymnast is considered to be entitled to one-eighth of the general cost of rent etc. for the use of his study for his clerical office, and perhaps some fraction between that and the one-half commonly applied to provincial practitioners might be reasonable.

Tax Payable after Retirement

"E. E. M." contemplates retiring from the Colonial Service and inquires what tax will be payable by him on £900 pension plus £1 100 interest.

* * * This calculation is as follows:

Total Income	---	£2 000
Deduct: Earned income allowance	---	£150
Personal allowance (married)	---	£225
Children (3)	---	£160
		£535
		£1 465
of which £225 chargeable at 2% tax	---	£22 10 0
and the balance £1,240 chargeable at 4%	---	£248 0 0
		£270 10 0

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to *The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1*.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are: *MUSEUM* 3561 3562 3563 and 3564 (internal exchange four lines).

The TELEGRAPHIC ADDRESSES are: EDITOR of the *British Medical Journal* Athology Westcent London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) Articulate Westcent London.

MEDICAL SECRETARY Mediucern Westcent London.

The address of the Irish Office of the British Medical Association is 15 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin) and of the Scottish Office 7 Drumshugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

MEDICAL TREATMENT IN CHINA

DR J. JONES (Bromley, Kent) writes in answer to Fleet Surgeon Home's inquiry in the *British Medical Journal* of August 4th (p. 228). Though I have been a medical missionary in China from 1905 to 1927 (excluding furloughs) and have served in four of China's provinces I cannot recall any Chinese telling me of the system of retaining fees for patients, which was discontinued during periods of ill health. Neither has my wife who has lived in China longer than I heard of that practice.

LETTERS, NOTES, ETC.

SUNSPOTS AND SUDDEN DEATH

SOME months ago (April 16th 1927, p. 750) we mentioned the hypothesis submitted to the Académie de Médecine by Dr M. Fauré, associating the appearance of the occurrence of acute crises in various chronic illnesses with the passage of spots over the solar meridian. Dr Fauré whose address is La Malou, Hémeil, France, now invites any interested to communicate directly with him with a view to the collection of clinical evidence. He undertakes also to notify in advance the transit of these sunspots.

ST THOMAS'S DIRECTORY

A NEW edition has been prepared of the *Alphabetical and Local List of Old Students of St Thomas's Hospital*. The greater part of this directory is arranged in two sections the first being an alphabetical list of names and the second a local list. Old St Thomas's men will welcome this compilation which is we understand, largely due to the industry of Mr Robert Hopkins.

BARLEY FOR INFANTS

MRS S. K. FEN ROBINSON and Co. LTD. of Norwich have revised the infant feeding directions and recipes on the container of their patent barley for infants and for making barley water and puddings bringing up to date the feeding recipes and simplifying the process of preparing feeds.

THE REPORT OF THE COMMITTEE ON VACCINATION

Correction

WE have been asked to correct two errors which appeared in the summary of the above report published in the *Journal* of August 11th. On page 267 line 21 from foot of the first column, majority should be minority. On page 268 line 10 from top of the first column, revaccinations should be vaccinations.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 35, 37, 40, 41, and 42 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 408.

A Paper

ON

THE DIAGNOSIS OF URETERIC CALCULI*

BY

ANDREW LULLINGTON, C.B., C.M.C., M.D., F.R.C.S.I.,

Professor of Surgery, Queen's University, Belfast Surgeon
Royal Victoria Hospital, Belfast

In opening this discussion I shall limit myself to an account of my own personal experience, confident that omissions in the presentation of the subject will be dealt with by others.

COMPOSITION OF URETERIC CALCULI

I have made a rough analysis of 35 ureteric calculi passed by patients or removed by operation. In no fewer than 29 of these—that is, in 80 per cent.—the main constituent was calcium oxalate. In 5 cases phosphates predominated and in one case only was there a preponderance of uric acid. If this experience is corroborated by others, the accounts given in the textbooks, which emphasize uric acid or urates as the chief constituent of renal and ureteric calculi, require modification.

CHARACTER AND EFFECTS

Ureteric calculi vary, of course, in size, shape, and colour. A very common type is small in size, irregular in shape and outline, with sharp edges, greyish or brown in colour, and often crystalline in appearance. The sharp, almost knife-like projections of these little calculi lacinate the delicate mucous membrane of the ureter in their passage and the calculi are liable to be held up at the points where the ureter narrows or changes its direction. Hence they are frequently arrested at the outlet of the renal pelvis at the vesical end of the ureter, and, much less frequently in my experience, at the hrim of the pelvis. It takes very little trauma to draw blood from the mucous membrane of the ureter. The passage of a smooth ureteric catheter even with the greatest care, is liable to be followed by slight haemorrhage, and if the catheter is retained for any length of time the specimen obtained from the ureter may be deeply blood stained. It is easy to account, therefore, for two, at least, of the signs and symptoms of ureteric calculus—namely, haemorrhage and pain. Haemorrhage is caused by laceration of the mucous membrane and pain by the irritation and consequent increased peristalsis of the ureter. Another cause of pain is the increased tension produced in the renal pelvis when the calculus causes a partial block of the ureter. A ureteric calculus rarely causes complete obstruction of the ureter. The urine tends to find its way past even a large calculus and may actually groove or tunnel it. The absence of an efflux from the affected side does not necessarily mean a mechanical block, it may be due to a reflex anuria. I have only once seen a complete mechanical block, and this occurred in a patient who had suffered from a tuberculous kidney for many years. The lower end of the ureter on the affected side was occupied by a large phosphatic calculus which had mushroomed into the bladder.

There is another remarkable phenomenon produced by the presence of these irregular foreign bodies in the ureter, and that is reflex polyuria on the affected side. Twenty years ago when the Association met in Sheffield at a discussion on the "Indications for nephrotomy and nephrectomy" I brought forward the subject of unilateral diuresis and gave several examples. Since then I have made some hundreds of observations, and the views then expressed as to the importance of this sign in diagnosis have been abundantly confirmed. Let me give a recent example.

A gentleman aged 45 about two months before examination began to complain of attacks of pain in the left side radiating downwards. The attacks were associated with vomiting and on several occasions with haematuria. When the urine was examined however on August 10th 1927 it was found to be chemically and microscopically free from abnormal constituents.

But in opening a discussion in the Section of Surgery of the Annual Meeting of the British Medical Association Cardiff 1928

except for a number of calcium oxalate crystals. On ureteric catheterization the flow on the affected side was found to be rapid and copious and the specimen had a specific gravity of 1005. On the sound side the flow was very scanty and the specific gravity of the specimen was 1015. A radiogram showed a small shadow possibly due to a calculus in the position of the lower end of the left ureter. About eighteen days after cystoscopy I had a severe attack of pain and three days later passed a small irregular calculus a little larger than a hemp seed. A week later cystoscopy was again carried out and the specific gravity was now 1015 on both sides and the quantity of urine equal on the two sides.

Note that in this case the urine at the time of examination was perfectly normal, and the only unequivocal sign incriminating the kidney was a definite polyuria on the affected side, which passed off when the calculus was got rid of.

Another case, in which a more detailed examination of the urine was made and which has already been published,¹ is the following.

A man aged 34 was seized ten days before examination with severe pain in the left loin radiating to the pubis. This passed off to recur again in a very severe form several times. Cystoscopy was carried out shortly after one of these attacks and catheters were passed into the ureters. The catheter on the left side encountered an obstruction a short distance up which was negotiated with a little difficulty. The flow from this side was vigorous and free while that from the right was sluggish and scanty. The specimen obtained from the left side had a specific gravity of 1010 contained 0.304 per cent of chlorides and 0.48 per cent of urea and was much greater in quantity than that obtained from the right side. That from the right side had a specific gravity of 1030 contained 0.836 per cent of chlorides and 2.16 per cent of urea and was discharged in drop depositing mites on cooling. A radiogram showed a small shadow about the site of a pin's head at the lower end of the left ureter. On the third day after cystoscopy a small speiculated calculus was passed per urethram and all pain ceased. Four and a half days later the ureters were again catheterized with the following result. There was now no demonstrable difference in the rate of flow and the specific gravity was 1015 on both sides. The specimen from the left side showed 1.45 per cent of chlorides and 0.84 per cent of urea while that from the right showed 1.40 per cent of chlorides and 0.78 per cent of urea. In other words the specimens on the two sides were almost identical. On both occasions there were a few red blood corpuscles in the specimen from the left side but there was no pus in either specimen.

In these cases of unilateral diuresis the jets on the affected side follow one another in more rapid succession than on the opposite side, and the quantity in each jet is larger in amount. There may also be some irregularity in the rhythm on the affected side. The specific gravity is estimated by glass beads, and the quantity necessary is about 4 to 5 c.c.m. Smaller quantities will suffice, but are more troublesome to work with.

For the purposes of this discussion I have looked up the notes of 50 undoubted cases of ureteric calculus occurring in my own practice. All except two of the cases were proved or presumed to be in the lower ureter, and all true renal calculi were excluded. In 20 of these the investigation just mentioned was carried out, and in no fewer than 14, or 70 per cent., an easily demonstrable diuresis, with diminished specific gravity of the specimen, was present on the affected side. In 3 cases no difference could be detected between the two sides, and in 3 again, probably reflex in character, was present. In one of the latter cases, on a second examination, though the calculus was still present, an abundant flow of dilute urine was obtained from the affected side. The calculus was subsequently removed by operation. When a calculus has been present for some time in a ureter hydronephrosis may result and it is desirable to know if the dilute urine which is secreted by a hydronephrotic kidney differs in any way from that due to diuresis. My colleague Dr. Mavis, who has been associated with me in this work, will deal with this point and will give the results of his examination of the urine in a number of cases.

While much has been written on calculous anuria very little has been said on the occurrence of unilateral diuresis from whatever cause produced. The explanation of both phenomena is afforded by a study of the nerve supply to the kidney and its influence on the blood flow. Through the splanchnic nerves the kidney receives vaso-constrictor and vaso-dilator fibres. The stimulus of a calculus may cause vaso-constriction and reduction or cessation of the secretion of urine on that side due to diminished blood flow through the glomeruli. On the other hand, it may cause vaso-dilatation, increased blood flow, and diuresis.

The latter is the more common occurrence. Cushny, in his work on *The Secretion of Urine*, discusses "pressure diuresis" seen in animals where one ureter is slightly obstructed, and states that it is almost certainly due to reflex vaso-dilatation. He suggests that a slight stimulus arouses a dilator effect, while a stronger one, such as the pain of a calculus, sets the more powerful constrictor in action, and thus leads to anuria. My observations go to show, however, that even with severe pain renal or ureteric calculus is much more commonly associated with diuresis than with anuria.

SIGNS AND SYMPTOMS OF URETERIC CALCULI

Pain

The chief symptom of a calculus in the ureter is pain, and it may be the only symptom present. Papan and Ambard² give some interesting facts bearing on renal pain to which a short reference may be made. The kidney receives its chief nerve supply from the splanchnic nerves through the renal plexus, and a branch from the first lumbar ganglion. The nerves to the kidney are, with few exceptions, non-medullated, while those

correspond in part to the kidney, the eleventh and twelfth dorsal and the first lumbar correspond to the pelvis and ureters. Certain reflex phenomena, such as nausea, vomiting, and pallor, with cold sweats, unassociated with disturbance of pulse or respiration, commonly accompany pain due to distension of the renal pelvis. Papan and Ambard are of opinion that renal pain is usually, as a matter of fact, "pyelic," and that obstruction of the ureter declares itself by renal colic due to distension of the pelvis. It would seem reasonable to assume, however, that increased peristalsis of the ureter, the result of an irritant such as a calculus, is a factor in the production of the pain known as renal colic.

The pain due to the passage or the arrest of a ureteric calculus cannot, I think, be distinguished from that due to a renal calculus lodged in the pelvis of the kidney. I have gone over the notes of my cases of ureteric calculus and compared them with those of known cases of renal calculus, and have come to the conclusion that the site and character of the pain may give no clue whatever to the size or position of the calculus. It is further evident from these notes that a precisely similar calculus may give rise in one

FIG. 1.—Ureteric calculus occupying a frequent position—that is opposite the ischial spine.

FIG. 2.—Ureteric catheter arrested by calculus.

distributed to the pelvis and ureter are for the most part medullated. The cells met with in the ganglia of the renal plexus are of the sympathetic type. It appears probable that renal pain issues from the sympathetic, the cells of which oppose an obstacle to impressions only overcome when these are of a violent nature. It is probable that painful sensations in the sympathetic system are really only perceived on quitting that system and gaining, by way of the innu communicantes, the posterior roots of the cord and through them the cerebro-spinal centres. Hence it is that pain is often reflected along the course of nerves connected with the corresponding innu communicantes.

Compared with the kidney, the pelvis and ureters are highly sensitive. Distension of the pelvis is very definitely painful. If more than 3 to 7 c.c. of fluid are injected into a renal pelvis, pain resembling renal colic is, as a rule, provoked and may at once be relieved by drawing off the fluid injected. The pain commences, as a rule, in the costo-lumbar region, or in the subcostal region in the anterior axillary line. Tender points can be demonstrated by touch in the costo-lumbar, subcostal para umbilical, and iliac regions. These areas are those to which pain is referred by the cerebro-spinal nerves from impressions received by the sympathetic. Pain may be referred along the course of the nerves of the lumbar plexus towards the thigh, the testicle or labia majora, or to the renal region of the opposite side. Zones of cutaneous hyperaesthesia may be demonstrated by stroking, pinching or pinching the skin. The tenth, eleventh, and twelfth dorsal segments

patient to the merest discomfort, while in another the pain may be of the severest character, radiating to the utmost terminations of the peripheral nerves. Again, a calculus may remain in the ureter for weeks or months and only periodically give evidence of its presence.

The pain in the cases that have come under my notice has varied very much in position, character, and severity. In a few vague discomfort only was complained of, referred to the back, or the side, or to the iliac region. In others attacks of typical renal colic occurred, the pain commencing in the costo vertebral angle and radiating downwards to the iliac region, the testis or vulva, the hip, the thigh, the rectum, the knee, or even to the foot. In some cases it was referred to the umbilicus or to the opposite side. In other cases the pain commenced in the iliac region and radiated upwards to the back and downwards to the lower part of the body. In others again the pain was stationary in the back or side or in the iliac region. In a case of renal calculus not included in this series, the patient, a woman aged 30, yelled with pain in the knee. In another case of renal calculus the pain started in the region of the left kidney and radiated to the shoulder and the back of the head. In a certain proportion of cases a note was made of rigidity, or at least of increased tone of the abdominal muscles on the affected side, but the board-like rigidity of peritonitis was never present. Tenderness over the kidney and ureters was frequently found. The pain when severe was often accompanied by vomiting, pallor, and cold sweats.

The pain may be of momentary duration or may last

for hours. It may begin gradually or suddenly and cease in the same way. It may occur in attacks with long or short intervals of complete freedom as it may be continuous. It may come on in the middle of the night while the patient is in bed or it may occur while he is walking about. In many cases it is aggravated by exercise. Hot fomentations frequently relieve it. Its character also varies, being described as an ache, a sense of discomfort, a gnawing or burning sensation, a bursting feeling or a feeling of fullness, a stab, a tearing or cutting sensation, and so on. It is generally easily distinguishable from the more familiar pain of intestinal colic.

I have been struck, in reading the notes, how often pain in the iliac fossa, either fixed or radiating, was complained of. Given a patient with a pain in the right iliac fossa, vomiting, and some tenderness and rigidity on that side, and it is easy to see how the case may be

FIG. 3.—Calculi in lower part of ureter and two in lower part of a hydronephrotic sac. Calculi are also present in the opposite kidney.

mistaken for one of appendicitis. The easy going diagnosis of chronic appendicitis is responsible for more errors than one cares to contemplate with equanimity. Frequently patients state that they have been operated on for appendicitis without relief. Before a surgeon commits himself to a diagnosis of chronic appendicitis a complete chemical and microscopical examination of the urine should be made. If still in doubt he may be saved from the chagrin of an unsuccessful operation by a cystoscopic examination and the discovery of significant changes at the ureteric orifice on the affected side, or a unilateral diuresis. Should an appendix at operation be found to be healthy or at least not sufficiently diseased to account for the patient's symptoms the abdomen ought not to be closed without a detailed examination, and in this the ureter should be included. The most frequent place in the lower ureter for a calculus to be arrested is at or near its entrance into the bladder, and this portion can be explored in a doubtful case by detaching the peritoneum from the pelvic wall so as to expose the ureter extraperitoneally. A catheter in the ureter from the bladder will much facilitate this exploration. If a calculus be found it can be removed and an abortive operation averted.

Frequency of Micturition

It is generally believed that when a ureteric calculus approaches the bladder its arrival is heralded by frequency of micturition and straining. This symptom however may be entirely absent. I removed a calculus about the

size of a date stone from the lower end of the right ureter in a woman aged 21 who did not have any frequency of micturition, also a large calculus, 3 inches long and 1 inch thick, from the vesical end of the left ureter in a boy aged 18½ years who had no frequency and no dysuria. In another case, that of a male aged 43, the calculus was actually seen by cystoscopy in the orifice of the left ureter, and yet there was no complaint of frequency or dysuria. On the other hand, I have seen many cases of calculus lodged in the renal pelvis in which frequency of micturition was present. All this tends to demonstrate how difficult it is by symptoms alone to locate a urinary calculus.

Rectal Tenesmus

One or two of my patients with a calculus arrested at the entrance of the ureter into the bladder have complained of rectal tenesmus.

Inflammatory Signs

The presence of a calculus in the kidney or ureter is liable to give rise to inflammatory changes, and infection by micro-organisms, generally the *Bacillus coli*, is not infrequent. In addition to pyelitis, ureteritis and peri-

FIG. 4.—Showing relation of phleboliths to bladder. The cystogram shows also a filling defect due to a tumour.

ureteritis at the point of arrest, leading to much thickening may occur. These changes are frequently associated with a rise of temperature and an increase in the pulse rate. A leucocytosis may be revealed on blood examination, and pus and micro-organisms will be found in the urine.

The Presence of Abnormal Constituents in the Urine

Haematuria may be the first symptom of a renal or ureteric calculus, and in rare cases the only symptom. I have pointed out that a calculus may be lodged in the ureter and yet the urine may fail to show any microscopical or chemical abnormality. In a case of suspected ureteric calculus, however, it is very unlikely that this state of affairs will continue. Frequent examinations should be made especially for blood which may perhaps be detected only by the microscope. The specimen for this examination should be taken without any instrumentation. A catheter, no matter how carefully passed, may draw microscopical blood and obscure the diagnosis. The meatus in both sexes may be carefully cleansed and contamination avoided by measures that will readily suggest themselves. The presence of microscopical blood is of more importance in diagnosis than a few pus cells having regard to the fact that the latter are so frequently found in the urethra. Pus and albumin in the urine are, of course, confirmatory tests and should always be looked for. The presence of crystals of triple phosphate, calcium oxalate, or uric acid is so frequent as to be of only secondary value in diagnosis, unless in great abundance.

EXAMINATION OF THE PATIENT

The patient will be examined for tenderness and swelling of the kidney, for tenderness along the course of the ureter, for tenderness of the testicle on the affected side without other obvious cause, often with a negative result also for the areas of hyperaesthesia to which reference has already been made. Rigidity of the abdominal muscles is more suggestive of an intra-abdominal lesion, but, as stated above, it may be present with renal or ureteric calculus. Besides appendicitis, acute and chronic, many other intra-abdominal conditions may give rise to symptoms more or less resembling those of ureteric calculus. Such are cholecystitis, gall-stones, gastric and duodenal ulcer, intestinal obstruction, colitis, tuberculosis and other infections of the abdominal lymphatic glands, and affections of the ovary and tubes. The surgeon's examination will include, therefore, a wide survey of the abdominal organs. Other affections of the kidney itself may give rise to symptoms indistinguishable from those of renal or ureteric calculus. Hydronephrosis, for instance, may give rise to typical renal colic as severe as that caused by a calculus. Renal colic may be present also in tuberculous and other infections of the kidney, malignant growths, hydatid disease, haematuria with clots, etc., and is due to the passage of clots or portions of growth or cysts down the ureter. In fact, any lesion that narrows or obstructs the ureter in any part of its course may give the symptoms of stone in the ureter, and these can be eliminated for the most part by cystoscopy, ureteric catheterization, ureterography, and pyelography.

A rectal or vaginal examination is a most important part of the examination of a suspected case of ureteric calculus. The stone can frequently be felt in the lower end of the ureter through the rectal or vaginal wall, or the ureter may be felt greatly thickened, as was found in the following cases. In a male, aged 22, with symptoms of renal calculus with vesical irritability I was able to feel through the rectal wall what I took to be a thickening of the lower end of the right ureter. The swelling was about the size of an almond. X-rays showed a well-defined ovoid shadow in this position. Operation disclosed a segment of ureter about three times the normal size, with thick walls enclosing a calculus about the size of a melon seed. In a girl, aged 21, with pain in the right iliac fossa radiating to the back and without vesical symptoms, the lower end of the right ureter could be felt greatly thickened per vaginam. At operation, the ureter just proximal to the bladder was found thickened to about the size of a plum stone, and a calculus about the size of a date stone was liberated from its interior. A thickened ureter, therefore, as felt per vaginam or per rectum, may be an important sign of an impacted ureteric calculus.

X-RAY EXAMINATION

Examination by x-rays is one of the most valuable means of diagnosis at our disposal, but many are the pitfalls. A discussion of this subject alone would occupy all the time at my disposal.

The shadow of a calculus varies according to its atomic weight and its density. Those composed of calcium oxalate give the deepest shadows, phosphatic stones come next, while uric acid calculi may give no shadow whatever (Hazard). Of the various opaque bodies likely to be mistaken for calculi in the urinary tract the most important from their position, size and shape are the phleboliths, the frequency of which has only been demonstrated since the use of x-rays for diagnosis has become general (see Fig. 4). Phleboliths are round or oval in shape, small and uniform in size, often bilateral, and situated, as a rule, below the great sciatic notch and lateral to the line of the ureter (Culligan). If multiple they are usually disposed in a linear fashion rather than in groups. The shadow of a phlebolith resembles closely that of a ureteric calculus, but the latter is more apt to be irregular in shape and outline. A very common situation for the shadow of a ureteric calculus is opposite to the ischial spine (see Fig. 1).

Calcified glands following on tuberculous infection are very common. The shadows given by these are generally larger, more irregular in shape and less dense than those of phleboliths. Some of the shadows may show areas of

greater density at the periphery in the form of rings or crescents. Calcified glands are collected into groups rather than rows, but isolated ones occur and may be difficult to distinguish from ureteric calculi. Calcification of the pelvic ligaments and mesos, faecal excursions or foreign bodies in the intestine and in the appendix, and retained foreign bodies, such as the missiles of war, have all been mistaken for urinary calculi.

To establish a diagnosis an ordinary radiogram is first taken, and if suspicious shadows appear the exact relationship to the kidney, ureter, and bladder is defined by an opaque catheter (see Fig. 2), or by a ureterogram, a pyelogram, or a cystogram. The value of this examination is greatly enhanced by stereoscopic radiography. It is obvious that the opaque catheter, for instance, may pass across the shadow of a body which is in front of or behind it. The exact relationship may be determined by knowing the shift of the x-ray tube and its distance from the plate in taking stereoscopic radiograms. Accurate calculation can then be made of how far a body giving a shadow is removed from the ureter or kidney. During the war this method proved invaluable, and surprisingly accurate localization of foreign bodies relative to the kidney and ureter was obtained in many cases. The value of a ureterogram or pyelogram when a shadow does not coincide exactly with the line of the opaque catheter is obvious. For instance, a ureter may be dilated and the shadow, though not touching that of the opaque catheter, may be seen to be covered by the shadow of the dilated ureter. Very striking results are sometimes seen by pyelography, as, for instance, in one of my cases in which, in addition to three shadows in the line of the lower ureter, two small oval shadows were seen far removed from the line of the upper ureter. Their significance was shown by pyelography, which demonstrated a huge hydronephrosis with two shadows at its lower limit. The diagnosis was obviously a couple of calculi which had gravitated to the bottom of a hydronephrotic sac (see Fig. 3).

I have laid some stress on the possibility of mistaking a case of ureteric calculus for one of appendicitis, but I have a specimen which shows how a diseased appendix may be mistaken for a ureteric calculus. In this case the x-ray report strongly suggested calculi in the ureter, and to make the diagnosis more difficult there was a slight difference in the urine from the two sides, that on the right having a specific gravity of 1015 as compared with 1020 on the left. In addition, the ureteric catheter encountered some opposition a few inches up on the right side. The urine on the affected side, however, did not contain pus which would almost certainly have been the case if calculi of the size suggested by the shadows seen in the radiogram had been present in the ureter. The appendix was therefore explored, and found to contain one large and one small concretion of the correct size and shape. The proximity of the appendix to the ureter in this case may have caused some obstruction to the passage of the catheter, hence the difficulty in diagnosis.

It is not uncommon to find calcified glands in the neighbourhood of the kidney or ureter, but it is not generally known, I think, that calcified areas may be present in the perineal or peri-ureteric fat. I have several specimens in which this condition was found, and will mention one example in which the x-ray report stated that there were four shadows in the renal region—one circular and three irregular in shape—probably calculi. When the kidney was explored I could only find one round-shaped calculus in the pelvis. After searching in vain for the other three I found in the perineal fat three irregular calcified masses corresponding in size and shape to the x-ray shadows. Here an opaque ureteric catheter and stereoscopic radiograms would have been of great assistance.

In passing the ureteric catheter it may be felt to hit against what appears to be an obstruction in the ureter. With a little manipulation it may or may not be made to pass on. This difficulty in passing the catheter is so frequently found in cases with no abnormality whatever in the ureter that it cannot be considered of any diagnostic importance. The tip of the catheter may catch, for instance, in a fold of the mucous membrane or be arrested by spasm. A ureteric calculus, even one of considerable

sive, may on the other hand, offer no obstacle to the passage of the catheter, and it may not even be felt as an obstruction.

CYSTOSCOPIC APPEARANCES

Looking over my case sheets I find that, in addition to the alterations in the rate of secretion and in the rhythm of the jets to which I have already referred, and the presence of blood or pus in the efflux, I have notes of certain changes at the ureteric orifice on the affected side as seen by the cystoscope: the following description is based on these notes. There may be no apparent departure from the normal the orifice remaining slit-like and free from surrounding vascularity or oedema. Thus there were no obvious changes in three cases in each of which a calculus was subsequently removed from the ureter, just proximal to its entrance into the bladder wall. In 20 out of the 50 cases however, definite changes were specially described. These consisted of the following.

Some departure from the slit-like shape of the orifice, which had become sinuous, oval, circular, or irregular in shape. In some cases the orifice was more patulous than normal. In a few the only noticeable change was increased vascularity, without swelling round the orifice. In the large majority however, there was a good deal of redness and oedema at and around the orifice. The opening of the ureter in some cases was completely obscured and perched on the top of a little mound or hillock of oedematous mucous membrane, and was only discovered by probing about with the tip of the catheter. The chief sign was therefore, alteration of the shape of the orifice,

associated with oedema at the spot and for some distance around. The orifice if not obscured often appeared like a dimple in the centre of a raised area of mucous membrane. In a few cases oedematous tags resembling minute papillomata were seen surrounding the opening. Occasionally flecks of lymph were seen on the lips or shores of purulent material projecting from the orifice.

A very characteristic sign was the presence of small haemorrhagic points and splashes around the orifice extending in some cases along the interureteric bar as well as laterally. In four cases the calculus was actually seen in the depths of the orifice or about to drop into the bladder. In five cases examined after an attack of pain the calculus was seen lying at the base of the bladder.

I have thus had the opportunity of observing what may be termed the birth of the calculus. The ureteric orifice has more than a fancied resemblance to the vulva and it is fascinating to watch the calculus like a foetal head advancing and breaching as in the act of parturition. Like my friends the obstetricians I have 'put on forceps' to assist nature and in a few cases I have even performed a miniature cephalotripsy. When the dystocia has been insurmountable I have like them, resorted to a form of Caesarean section and finally, again like them, I have been amply rewarded for my trouble by the effusive thanks accorded to me when I have presented to the author of its being the fruit of his loins.

ENCEPHALO-MYELITIS IN VIRUS DISEASES AND EXANTHEMATA*

BY

HUBERT M. TURNBULL, D.M.

Director of the Bernhard Baron Institute of Pathology the London Hospital.

THE HISTOLOGY OF POST-VACCINAL ENCEPHALITIS

I UNDERSTAND that the primary subject of the discussion is the nature of encephalo-myelitis following vaccination. It is no longer necessary to argue that an encephalo-myelitis is sometimes a complication of vaccination. The exact cause of the encephalo-myelitis need alone be discussed.

Is the encephalitis caused by the virus of vaccination lymph, or by some other infection introduced at vaccination, or does the vaccinal virus excite some latent infection? If the encephalo-myelitis is the result of an infection introduced at vaccination or excited by the vaccination, are the resulting histological changes due to the action of the introduced or excited infection alone or to the combined action or the interaction of such an infective agent and the vaccinal virus?

In finding an answer to these questions a great many methods are of service, one of these is comparative histology. To that method my remarks will be confined.

The histological changes in post-vaccinal encephalitis have been remarkably uniform in all cases which I have seen or of which I have read a description. The case of Paul (1923) may be an exception. I have not had access to the description of this actual case, but only to that of the example of severe poliomyelitis in which, he says the changes were astonishingly similar. The description of seven brains and cords given by Turnbull and McIntosh (1926) amplified that of two brains by Bastiaanse (1925) and has in turn been confirmed, amplified and in one point corrected by the descriptions of three brains and cords by Perdrau (1928) of one brain and cord and one segment of brain by Schürmann (1928) and of three brains by Luksch (1927) in his later paper. I have subjected the formaldehyde-paraffin material from the first four of our seven cases to other stains, particularly Victoria blue and Mallory's phosphotungstic haematoxylin with the

latter not only can the fibroglia and myelin be stained but the bodies of the proliferated glial cells are sharply defined. A further case was obtained by Dr Woods during my holiday in September 1927: a male of three months who became ill on the tenth day after vaccination and died on the twenty-fifth day. In this example, which for convenience may be referred to as our Case viii, the condition was subacute as in our Case iv.

To the naked eye congestion and oedema are visible in most examples: haemorrhage into the leptomeninges and subdural space of the brain one or two punctiform haemorrhages into the spinal cord and blurring of the demarcation between the grey matter and white matter of the cord have been observed in some examples (Turnbull and McIntosh).

Microscopically focal histological changes extend from the cortex of the brain to the lumbosacral cord. The incidence was maximal in the lumbosacral cord and the pons, and was least in the upper cervical cord of our first seven cases. Case viii differs in that the affection of the spinal cord is greatest in thoracic segments there it is of great severity. Perdrau found the most severe lesions in the pons and upper medulla and the maximal lesions in the spinal cord in the lower thoracic segments and the lumbosacral enlargement. Schürmann found the maximum in the pons and medulla. Luksch (brain and brain stem) in the pons and substantia nigra we found the inflammation in the mid brain to be greatest in the substantia nigra. Schürmann found a fairly severe affection of the optic tract and nerves.

We found the white matter in the cerebrum to be more affected than the grey but in the central nervous system considered as a whole we estimated that the grey matter was more affected than the white. Perdrau found the white to be most affected in the cerebrum and cerebellum but the grey in the brain stem and spinal cord. In the brain and brain stem Bastiaanse considered the white matter to be most affected. Luksch the grey and white to be about equally involved.

The histological changes can be divided into acute and subacute types. The acute type is usually found in patients who die from fourteen to seventeen days after vaccination and the subacute in those who survive longer.

In the acute type there is a slight, intermittent infiltration of the leptomeninges chiefly about veins, with small and large lymphocytes, plasmacytoid and true plasma cells, large mononuclear leucocytes and endothelial cells. The

* Read in opening a discussion in the Section of Pathology and Bacteriology of the Annual Meeting of the British Medical Association Cardiff 1923.

vessels are engorged, and frequently contain thrombi, occasionally there are haemorrhages. Within the central nervous system engorgement is again found, thrombi are occasionally met, haemorrhages are rare, and are small and perivascular. The essential change consists of perivascular and marginal zones of demyelination. After describing these zones of demyelination we unfortunately named them zones of "softening"—a term generally regarded as indicating complete colliquative necrosis in addition to rapid demyelination. We also described the occurrence of areas of infiltration without demyelination in the grey matter and very rarely in the white. I have stained my series again, and find, as Perdrau did, that there is some demyelination in all the zones without exception, for instance, round the vessel in fig 2 of our paper. The only extra-adventitial infiltration without demyelination is found in places such as the pons, where there is a diffuse proliferation of glial cells between numerous adjacent areas of demyelination.

The perivascular zones of demyelination (Figs 1 to 4) form wide sleeves which surround vessels, almost always veins, for long distances and extend along their branches. The marginal zones are found most frequently along the edges of the ventral fissure of the spinal cord, but also in the remainder of the periphery of the cord (Fig 4). Schramm found them also beneath the pia of the brain,

and very deeply stained they then give a positive reaction for fibrin with Weigert-Gram. This thickening I believe to be due to a fibrous inhibition, and not to proliferation, I have seen the same change unaccompanied by any other beneath the pia in a cerebral sulcus. Usually the limiting membrane is unaltered or rarified. Further from the vessel the fibrils form a wide-meshed net, and frequently appear to be diminished in number. The changes in the marginal zones are similar, except that I have not seen fibrinoid thickening of the limiting membrane.

Perdrau has found an incipient demyelination free from glial cells round many vessels. But in the conspicuous perivascular and marginal zones the wide-meshed net of glial fibrils usually contains, in the acute cases, a great number of proliferated glial cells. A few fibrous astrocytes are present, but not more than normally. The bulk of the cells have a relatively abundant cytoplasm, and are polygonal, round, or oval. The nuclei vary greatly in shape and depth of stain; various forms of degeneration to complete disappearance are seen. The cytoplasm is usually vacuolated, and may be foam-like. By Hottel's method Perdrau has found these cells to be microglia, and by Horzheimer's method he proved the presence of fat within them. The cells contain myelin as well as fat. In addition to these glial cells there are neutrophil leucocytes where the inflammation is exception-

the brain stem, and the optic nerves and tracts. Further, he found a similar zone beneath the epudyma of the lateral ventricles.

The zones of demyelination appear under low magnifications sharply defined, especially the perivascular zones. Within them demyelination is usually complete, except at the margin. Only a fraction of the axis cylinders survive (Perdrau, Schramm). The glial fibrils immediately round the vessel—the vascular limiting membrane—are sometimes thickened, form an abnormally close feltwork, and

FIG 3.—Perivascular demyelination in white matter. Posterior white column thoracic cord. Case I male, 15 years. Weigert's iron haematoxylin and van Gieson. 1/5 in obj. oc. Zeiss 4.6. (From the British Journal of Experimental Pathology.)

ally intense. Amphocytes and plasmacytoid cells are rarely present. Proliferated glial cells extend to a variable distance beyond the zones of demyelination and cause a diffuse infiltration in the most severely affected regions.

The adventitial sheaths of vessels occasionally contain coagulated albumin, even when there is no other change in the adventitia or surrounding tissue. Infiltration of the adventitia (Fig 3) is an inconspicuous feature, and is frequently absent from vessels surrounded by zones of demyelination. The infiltrating cells are large and small

lymphocytes, plasmaeoid cells, plasma cells, large mononuclear leucocytes, and cells with a fibrocytic type of nucleus. The number of plasma cells here and in the meninges is in some cases sparse.

In addition to perivascular and marginal demyelination Perdrau in Marchi preparations found degeneration of isolated fibres scattered throughout the central nervous system, especially upon the ventral surface of the corpus callosum. He also found degeneration of isolated fibres in the posterior roots. In our subacute Case viii there are conspicuous areas of demyelination in the anterior roots in the ninth thoracic segment. The root ganglia may be slightly infiltrated (Perdrau) or unaltered (Turnhill and Melutosh, Schürmann). The bodies of the neurons are astonishingly well preserved (Fig 2). There is often clumping of neuro-chromatin or tigrolysis, but loss of angularity and complete necrosis are very rare. Bastianse alone has described neuronophagia, in the *locus niger*.

In the subacute type the changes have usually continued for a longer period, consequently the adventitial sheaths are distended with a mosaic of large fat-granule cells. In Case viii these cells have completely replaced the small round cells in almost all sheaths, and they extend into the

FIG 4.—Perivascular and marginal zones of demyelination, large area of confluent demyelination in left lateral column and grey matter. Ninth thoracic segment. Case viii (subacute) male, 5 months. Weigert Pal.

leptomeninges, where they are very abundant opposite the most affected areas (Fig 5). The perivascular zones of demyelination may be scanty and narrow, or may coalesce to form large areas, as in Perdrau's Case ii and our Case viii, in which there is almost complete demyelination of the lateral column and grey matter on the left side of thoracic segments (Fig 4). The changes in the glia, particularly the fibroglia, in this later stage are obviously important in estimating the relation of the condition to disseminated sclerosis. I regret that an investigation of the glial changes in our Cases ii and viii is not yet (June) finished.

According to these histological changes post-vaccinal encephalitis is as we reported in 1924, clearly distinct from polymyelitis and oncephalitis lethargica and belongs, as Perdrau and Schürmann emphasized, to the group of conditions which are characterized by demyelination. Certain examples of the disseminated myelitis of Westphal (1874), disseminated encephalo-myelitis of later writers, disseminated sclerosis, and encephalitis periaxialis diffusa of Schilder (1912).

There can be no doubt that a condition resembling post-vaccinal encephalitis has occurred independently of recent vaccination and observed exanthemata. Kussner and Brosin (1886) described accurately identical changes in the cord of a man who had suffered for a year from chronic gonorrhoea. The changes described in the cord in the first case of Francotte (1890) appear to be similar, whilst Krabho (1913) described the changes in the brain. Very

similar but more chronic changes were described by Dreschfeld (1894). Wohlwill (1928) said that he had observed changes identical with these of post-vaccinal encephalitis in a patient who was not suffering from any known infectious disease. In the last two years in Germany a large number of cases have been observed, for instance by Redlich (1927), which resemble post-vaccinal encephalitis clinically. Similar cases have been observed in London by Hunter and Bruin (1928). The histological changes found by Redlich in a patient who died after an illness of four and a half months appear to have resembled those of the acute form of disseminated sclerosis more closely than those of post-vaccinal encephalitis. I have commenced the examination of one of the London cases—a boy of 5 years who died after an illness of three days. I can only say that as yet (June) congestion, oedema, and a few small perivascular haemorrhages have alone been found.

Similar histological changes have been found in affections of the central nervous system complicating exanthemata. Wohlwill (1928) has described two cases complicating measles, the only difference from post-vaccinal encephalitis was the absence in the first case of adventitial and meningeal infiltrations. In other cases the encephalitis complicating measles appears to have differed in being essentially haemorrhagic (Winnicott and Gibbs 1926, Musser and Hauke, 1928). The changes in the case of

FIG 5.—Large fat-granule cells in pia and vascular sheaths, small fat-granule cells in pale perivascular and marginal zones of demyelination and in large confluent area of demyelination in left lateral column. Sixth thoracic segment. Case viii (subacute) male 3 months. Busch Marchi.

Barlow (1886, 1887) were of yet another kind, if the description can be trusted. There can be little doubt that a similar encephalitis may complicate small-pox in view of the changes described in the cord by Westphal (1874) in two cases and by Eichorst (1913) in one. I have not found an adequate description of encephalo-myelitis in numps and chicken-pox.

Finally in paralysis complicating antirabic treatment the conditions found by Fielder (1914-15), Jochmann (1913), and Babes and Mirouesco (1908) appear to be those of post-vaccinal encephalitis although the descriptions lack precision.

Changes resembling those of post-vaccinal encephalitis have, therefore, been found complicating measles as well as, perhaps small-pox have probably complicated Pasteur's antirabic treatment, and have been found in cases in which there was no evidence of recent vaccination or of an exanthem.

As regards the nomenclature of this group of cases, most of the earlier examples quoted were called acute disseminated myelitis, the cord alone having been examined. It would appear correct therefore, to call the condition 'acute disseminated encephalo-myelitis'. This term, however, has been applied to cases which can be distinguished from the post-vaccinal group histologically (Wohlwill, 1928), and are regarded by many as the acute form of disseminated sclerosis (Anton and Wohlwill, 1912). To avoid confusion, therefore, it would be advisable to use the

term "disseminated encephalo-mylitis of the post-vaccinal type." The question of the relation between acute disseminated encephalo-mylitis of the post-vaccinal type, acute and chronic disseminated sclerosis, and encephalitis periaxialis diffusa is one which others here are more competent to discuss. In the above remarks I have placed in one group the cases of post-vaccinal encephalitis with those which appear to have shown essentially the same histological picture, and have separated this group from acute disseminated sclerosis. Wohlwill (1928) has pointed out the cardinal point of differentiation—the whole length of a vessel is surrounded by demyelination in the former and only a segment in the latter. But the pathogenic processes are essentially similar consequently the different pictures may simply represent modified reactions to a single agent and the histological differentiation be artificial. I find it impossible to consider acute and chronic disseminated sclerosis to be other than varieties of one condition—transitions between the two and mixtures of the two have been the rule rather than the exception in my experience.

ENCEPHALO-MYELITIS IN VIRUS INFECTIONS AND EXANTHEMATA

AN EXPERIMENTAL AND PATHOLOGICAL STUDY *

BY

JAMES MCINTOSH, M.D.

(From the Bland Sutton Institute of Pathology, Middlesex Hospital, London W.1.)

THAT an encephalitis or an encephalo-mylitis is at times liable to appear during certain acute infections has been known for some considerable time. Our knowledge, however, of the exact nature of this complication in some cases is very scanty. Encephalo-mylitis, whether primary or secondary, may be divided into two main groups—(a) purulent and (b) non-purulent. The purulent form is the result of the localization of some pyogenic bacterium in the brain substance while the non-purulent is usually the result of a virus infection, and it is this form which is under discussion to-day. Encephalo-mylitis is found in such virus infections as poliomyelitis, encephalitis lethargica, small pox, vaccination, chicken-pox, measles, mumps, typhus, etc. and with these I propose to deal in the above order.

POLIOMYELITIS

Symptoms suggestive of cerebral irritation are not uncommonly met with in cases of acute anterior poliomyelitis, while in a few instances a definite encephalitis occurs, and to this form the name cerebral poliomyelitis has been applied. True cerebral poliomyelitis, however, is relatively rare, thus Wickmann, in the great Swedish epidemic of

1905, did not see any definite cerebral cases, and none were recorded by Peabody, Draper, and Dochez in the great New York epidemic of 1909. The first cases were described by Stimpell in 1884, and to them he gave the name poliomyelitis, but in the light of our present knowledge it seems very probable that many of his twenty-four cases were not cases of true poliomyelitis. It is certainly true that in the majority of the fatal cases of poliomyelitis small focal areas of encephalitis can usually be demonstrated in the cortex to the brain, while in the experimental disease in monkeys, although the major lesion is always in the cord, focal areas of inflammation can be found in the brain.

My own investigations have convinced me that an extensive cerebral involvement in acute anterior poliomyelitis is unusual and, as a rule, the lesions in the brain are slight and mainly consist of a few scattered areas of perivascular cellular infiltration of vessel sheaths.

Experimental Disease

An experimental infection can readily be produced in monkeys by the inoculation of infective material from cases of poliomyelitis. The animal develops, after an incubation period of about a week, a very definite flaccid paralysis, and histological lesions in the cord identical with those in human cases are found. The maximal lesion is always found in the cord, no matter how the infection is made. In most cases isolated lesions are also to be found in the brain, and particularly in the grey matter at the base. Rabbits can also be infected, but with some difficulty.

ENCEPHALITIS LETHARGICA

In encephalitis lethargica the main pathological lesion is an encephalitis of varying intensity, but, as a rule, most marked in the basal ganglia of the brain, while the cord is generally unaffected. The most characteristic histological lesion is a well marked perivascular sheath infiltration, forming at times quite a distinct cuff round the vessel. The infiltration consists chiefly of lymphocytes with a number of plasma cells. Polynuclear leucocytes are conspicuously absent. In addition, there is a certain amount of infiltration of the perivascular penechyma and glial proliferation. The nerve cells are usually not affected.

Experimental Disease

As is generally admitted, encephalitis lethargica appears to have been unknown till the outbreak recorded by von Economo in 1916 in Vienna. I had the opportunity of examining some of the earliest cases which occurred in this country, and early came to the conclusion that we had to deal with an entirely new lesion and disease. In collaboration with Professor Turnbull, I was successful in inoculating material from an acute outbreak into monkeys and rabbits, and reproducing symptoms and lesions which showed great similarity to the natural infection in man.

Some writers have confirmed our findings while others have failed to do so, and base their arguments mainly on two grounds: (1) failure to produce any lesion at all, and (2) that lesions found in the experimental rabbit are due to the spontaneous encephalitis of rabbit, and not to the inoculum. But the great similarity of the lesion in man to that of the experimental disease in rabbits may be seen in photomicrographs, while histologically the spontaneous encephalitis of rabbits is quite another type, and no one familiar with the two lesions could use the second argument.

SMALL-POX

Clinical accounts of small-pox contain frequent references to the appearance of symptoms which suggest involvement of the nervous system. For instance, there may be convulsions and delirium during the first fever or during the eruptive stage while later there may appear definite parietic manifestations. A full account of the literature dealing with nervous complications of variola has been given in an earlier paper by Professor Turnbull and myself, so it is unnecessary to give it in detail here.

Fortunately, owing to the kindness of Dr. Carrow, medical officer for Chesterfield, I was able to examine the brain of a child who developed cerebral symptoms after

an attack of mild small pox. Histologically, a very definite type of encephalitis was found.

The histological lesion consists of a perivascular small cell infiltration characterized by a slight infiltration of the vessel sheath and a more diffuse wide infiltration of the surrounding parenchyma, which often shows well marked demyelination of the nerve fibres. The cellular infiltration is composed mainly of large cells with oval clear nuclei, together with a number of lymphocytes. Polynuclears are uncommon as also are plasma cells. The meninges are only slightly involved.

The general appearance of this inflammatory lesion is very striking, and the sharply demarcated vessel, with the surrounding cellular infiltration arranged in an irradiating manner is strongly suggestive of a tissue culture.

In this case the encephalitis was apparently diffuse in the upper brain, but gradually lessened as one passed down, till in the medulla there was no sign of it. Unfortunately the cord was not obtained for examination. The striking similarity of the lesion to that of post-vaccinal encephalitis will be referred to again.

POST-VACCINAL ENCEPHALITIS

In recent years a new type of encephalitis has been observed in relation to vaccination: the main clinical and pathological features of which Professor Turnbull has just given you. The occurrence of this particular type of case was noted by him as long ago as 1912 when we were investigating an epidemic of poliomyelitis. In 1926 Professor Turnbull and I published a paper recording our investigations on six cases of this particular post-vaccinal encephalitis. Altogether now some hundreds of similar cases have been published in Europe by Bastianse, Luksch, and others.

As the condition has been fully described by Professor Turnbull I shall content myself with indicating the features which I think have an essential bearing on the etiology of the condition. It is now generally admitted that post-vaccinal encephalitis bears a very constant relation to vaccination both as regards time and place. The condition manifests itself on the average 10 to 14 days after vaccination as headache, delirium, paresis, and ultimately coma and death in the fatal cases.

There has been considerable division of opinion as regards the true nature of this encephalitis, among these opinions two are worthy of mention.

- 1 That the disease is vaccinal in origin.
- 2 That the condition is due to the presence of a dormant virus stimulated into activity by the vaccination.

It has been suggested that the dormant virus might be poliomyelitis, encephalitis lethargica, herpes febrilis or some unknown virus. Neither time nor space allows of a complete analysis of the various views, so I propose to give only those data which I think have a direct bearing on the problem.

Histological Data

An examination of the lesions of the central nervous system shows that they present a very constant and characteristic histological picture, the main features of which might be summarized much as follows:

- 1 Wide distribution of lesions in grey and white matter of the brain and cord.
- 2 Perivascular nature of the lesion.
- 3 Slight vessel sheath infiltration with considerable extra vascular parenchymatous infiltration.
- 4 Infiltration composed mainly of large endothelial type of cells and glial cells.
- 5 Perivascular areas of softening or demyelination. Here as in post-varicellar encephalitis the general appearance of the perivascular cellular infiltration is suggestive of a tissue culture growth.
- 6 Occasional presence of small focal lesions in the internal organs.

The above lesions, I think, are sufficient to show that we have a new pathological entity, in that the lesions are distinct from those met with in the known virus

infections of the central nervous system—poliomyelitis and encephalitis lethargica. But in order completely to incriminate the virus of vaccinia it is essential that lesions of a closely similar nature can be produced by animal inoculation.

Experimental Data

Material from the central nervous system of these cases of post-vaccinal encephalitis was inoculated (a) intracerebrally and (b) intracutaneously into rabbits and monkeys. The intracerebral inoculations only produced a slight rise of temperature and some transient paresis, but by special intradermic inoculations into rabbits it was possible to recover vaccinia virus on several occasions. The negative nature of the intracerebral inoculations, to my mind clearly demonstrates that neither the virus of encephalitis lethargica nor that of poliomyelitis is present and I think that that of herpes febrilis might be included also as it has a distinctive lesion and so readily affects rabbits.

The actual presence of the vaccinia virus is not absolute proof, however, that the condition is solely due to the vaccinia virus as under normal conditions vaccinia virus can be demonstrated in the blood for some days after the vaccination has reached its height. The real proof would be the production of a similar lesion by the inoculation of vaccinia virus, thus conforming to the so-called postulates of Koch.

What, then, is the effect of intracerebral and intravenous inoculations of vaccinia? It has been known for some years that intracerebral inoculations of vaccinia virus into rabbits produces a fatal encephalitis of varying severity, and that there is considerable difficulty in carrying on the inoculations in series (Morie). Levaditi, however, a few years ago, succeeded in raising the virulence of a strain of vaccinia to such a degree that it could be successfully carried on from one animal to another. To this strain he gave the name of neuro-vaccine. The lesions produced in the brain are more meningeal than encephalitic and frequently show large areas of necrosis in addition.

My own experiments confirmed the above, in that at first I found it easy to produce an encephalitis with ordinary strains of vaccine lymph, but quite impossible to make passages in series. After many attempts, however, I succeeded in raising the virulence for rabbits of a freshly isolated various strain of vaccine lymph by rapid passage on the skin of the rabbit. This vaccine lymph was of such a virulence that frequently a general eruption, with internal focal lesions followed in the rabbit after simultaneous inoculation.

With the same virus I made a series of intracerebral inoculations, and then found that by this procedure I had got a very highly neurotropic strain for the rabbit. Intracerebral inoculations regularly produced a fatal issue in four to five days, and on examination of the brain very characteristic histological changes were observed. In contrast to what I found before, there were very definite areas of encephalitis in the brain, extensive meningeal lesions and, at times definite indications of perivascular softening. In addition the etiology of these lesions was of the type characteristic of post-vaccinal infiltrations.

These results at once invalidate Levaditi's failure to produce comparable lesions in rabbits' brains with his neuro-vaccine a negative result which he used as an argument against the varicolar nature of the post-vaccinal encephalitis.

Further I found that intravenous inoculations of Levaditi's neuro-vaccine and of my own high virulent vaccine lymph produced focal lesions in the internal organs of the rabbits. The lesions are to my mind absolutely typical of the lesions I found in the organs of cases of post-vaccinal encephalitis and, to judge from the written descriptions are similar to the focal lesion that occurs in true small pox.

The focal lesions were described many years ago as occurring in the internal organs of fatal cases of small pox but the histological descriptions are poor and somewhat difficult to visualize. So far as can be gathered there is no modern histological investigation recorded. For some

reason or another it is impossible to obtain pathological material from fatal cases of small-pox. The focal lesions in small pox are described by Weigott, Chiari, Roger, and Weil, the focal areas can be seen with the naked eye as pale areas about the size of a pin, non-purulent, with central necrosis.

The focal areas observed in cases of post-vaccinal encephalitis are visible to the naked eye, whitish in colour, and somewhat larger than, or about the size of, milium tubercles. Their general and histological appearance is at first sight suggestive of a tubercle. They differ in that they show more evidence of healing (fibrosis) than is usually found in tubercles, giant cells are prominent features, with a surrounding zone of fibrosis and lymphocytes. The fact that no tubercle bacilli could be demonstrated in the lesions, and the evidence of healing, strongly support the view that they are not tubercles, but granulomata resulting from multiple foci of some virus.

The following summary, based on the above experiments, suggests, I think, that vaccine virus is the causal agent.

1 Intracerebral inoculations of neurotropic strains of variolous lymph produce an encephalitis in rabbits, presenting the main histological characters of post-vaccinal encephalitis.

2 Intravenous injections of neurotropic strains of vaccinia produce focal lesions in the internal organs similar to those found at times in cases of post-vaccinal encephalitis and in variola.

3 The failure to produce any of the known virus infections of the central nervous system by animal inoculation with the material from post-vaccinal encephalitis.

4 The occurrence of a very similar cerebral lesion in a case of encephalitis following on small-pox.

CHICKEN-POX, MEASLES, MUMPS, AND TYPHUS

Encephalitis, as I have previously pointed out, has been recorded in cases of chicken-pox, measles, and mumps, but such a complication is rare.

In the case of chicken-pox (varicella), clinical records show that symptoms suggestive of an involvement of the central nervous system occur from time to time, and in the literature some dozen cases of encephalo-myelitis have been recorded. An excellent summary of these is given in a recent publication by Wilson and Foid, who record three cases which came under their own care. Recovery in most instances was complete in a few weeks' time. Fatal cases of chicken-pox are rare, so that no histological details are available, so far, I have only had the opportunity of examining the organs from one case of small-pox and, unfortunately, in that case the brain was not available.

Nervous involvement in measles and mumps is still more rare. Recently Wohlwill has recorded two cases of encephalitis during measles, and the histological changes are believed to show considerable resemblance to those found in post-vaccinal encephalitis. But I must reserve my judgement until I have had a chance of examining his work in detail.

Encephalitis in typhus fever is a constant feature, and may, therefore, be regarded as part of the actual disease process. Microscopical examination shows the constant presence of lesions in the central nervous system and internal organs. In general the encephalitic lesions show a great similarity to those of post-vaccinal and post-variolar encephalitis. The pathological changes have been described by Ceelen, Nicol, Spielmeyer, Walach, Todd, and Palfrey, and consist essentially of proliferations of large clear cells into the surrounding nerve tissue with infiltration of inflammatory cells (plasma cells, lymphocytes, and a few polymuclear leucocytes).

Four types of lesions are described, but the two most characteristic are the "compact" (tubercle-like) nodules of cells, and the "rosette" or diffuse perivascular outgrowth. The proliferated cells are generally considered to be glial in origin, but Wolbach and his co-workers are of the opinion that they are mesoblastic and derived mainly from the blood vessels.

As a rule, gross lesions are not visible to the eye, and the meninges show only a slight inflammatory infiltration.

Experimental Disease

Typhus has been experimentally transmitted to monkeys (cercopithecus) by intraperitoneal injections of blood from cases of the disease, and to guinea-pigs by injection of pathological tissue and lice from human cases. The virus can be carried on from guinea-pig to guinea-pig indefinitely by injection. Lesions are found in the central nervous system of these animals identical with those found in man.

SUMMARY

A non-suppurative encephalo-myelitis can occur in a number of virus infections—in particular, poliomyelitis, encephalitis lethargica, small pox, vaccinia, chicken pox, measles, mumps, and typhus fever.

In the case of poliomyelitis, localized areas of encephalitis are not infrequently found in fatal cases and, histologically, the lesions are typical of that known to occur in poliomyelitis.

In encephalitis lethargica the encephalitis is constant and a normal feature of the infection, with characteristic histological lesions.

The encephalitic complication is exceedingly rare in chicken-pox, measles, and mumps, and we know very little about the lesions produced.

In vaccinia and small-pox a very characteristic and diffuse encephalo-myelitis is found. Histological and experimental research have shown that the lesions in the two conditions are identical, characteristic, and definitely distinct from those of poliomyelitis and encephalitis lethargica.

The only virus that could be demonstrated in post-vaccinal encephalitis was vaccinia. Certain strains of vaccinia virus will produce in rabbits a vaccinal encephalitis showing the same type of lesion. These facts lead strongly to the belief that the lesions of post-vaccinal encephalitis are characteristic of the action of the virus of vaccinia on the central nervous system.

An encephalo-myelitis is apparently present in all cases of typhus fever, and here again the histological picture is distinctive, although there are resemblances to those met with in post-vaccinal encephalitis.

GENERAL CONCLUSIONS

We have seen, therefore, that encephalo-myelitis may occur during the course of several virus infections, either as part of the disease process or as a complication, and investigations of these conditions show that a histological picture of a certain type can be assigned to each. Doubtless further studies will bring forward additional new types as the differential features are better understood. This is well illustrated in the case of encephalitis lethargica and post-vaccinal encephalitis, each of which have been ascribed by certain writers to causes other than its specific virus.

The characteristic histological appearances of these conditions, together with the fact that lesions comparable with those found in the natural disease can be reproduced experimentally in animals by the inoculation of virus-containing material, is strong evidence that the encephalitis is actually produced by the infecting virus in each of the above-mentioned diseases.

PREVENTION AND TREATMENT OF DIPHTHERIA

BY

J. D. ROLLSTON, M.D., M.R.C.P.,

Medical Superintendent, Western Fever Hospital, London

THE unflinching interest taken in the subject of the prevention and treatment of diphtheria, which appeals alike to the general physician, pediatrician, hygienist, and bacteriologist, is shown by the fact that this is the fifth time within two and a half years that I have been honoured with an invitation to open a discussion more or less directly connected with the subject. A certain amount of repetition of what I have said on previous occasions is therefore inevitable, but I have endeavoured to bring my remarks up to date.

The question of prevention may be considered under two headings—namely, (1) general measures, including isolation, disinfection, and treatment of the carrier, and (2) specific immunization.

GENERAL MEASURES

Although it is doubtful whether isolation of diphtheria patients in special hospitals has had much effect in reducing its incidence, there is general agreement among sanitary authorities that diphtheria is a disease which, more than any other of those admitted to fever hospitals, requires such treatment. Not only does the laryngeal type of the disease need close and skilful supervision, but the prevention, detection, and treatment of the various forms of post-diphtheritic paralysis are best carried out by a resident medical and nursing staff.

As regards disinfection, there is a growing tendency, which is carried out in practice by several medical officers of health, superintendents of fever hospitals, and other sanitary authorities, to discredit the value of terminal disinfection after diphtheria, and to regard the living carrier, whether actually suffering from diphtheria or not, as responsible for the spread of the disease.

The period of isolation of a diphtheria patient should be determined by clinical considerations. In the absence of any discharges from the nose or ear, or acute inflammatory condition of the throat, a patient who has had a mild attack may be set at liberty at the end of a month. In cases of any degree of severity the period of detention should be prolonged to at least six weeks, most of which should be spent in bed, as during this time some form of paralysis is likely to develop. In the great majority of cases the throat becomes free of diphtheria bacilli within a few days after the membrane has disappeared, and only a small minority persist as carriers of virulent bacilli.

No uniformly successful method has been discovered for putting an end to the carrier state. Various lotions, gargles, and pastilles have been tried, with a varying degree of success, but the results are not convincing. The persistence of the carrier state is usually due to some local infection, such as chronically inflamed tonsils and adenoids or affection of the nasal sinuses. This is strikingly proved by the most efficacious if not the only remedy for the carrier state apart from the *vis medicatrix naturae*, being tonsillectomy and treatment of sinus infections. Tonsillectomy, however, and other surgical measures are not always practicable, nor, indeed, universally successful. In the absence of any morbid condition of the throat and nose the practice of insisting on one or two negative faecal and nasal cultures before discharging a patient is merely illusory, as owing to the frequent occurrence of intermittency in the carrier state a false sense of security may be afforded by such cultures. In their recent investigation J. E. McCartney and W. Harvey did not consider a carrier as free from bacilli until six consecutive examinations, spread over a period of six weeks, produced negative results.

As it has been found that the return case rate in those hospitals which have abandoned the practice of swabbing patients before discharge is no higher than in those in which it is still observed, since my appointment as medical

superintendent two and a half years ago I have discontinued the practice at my own hospital without finding that this discontinuance was followed by an increase in the return case rate.

SPECIFIC IMMUNIZATION

No invariably effective method being available for putting an end to the carrier state the most reliable method of prophylaxis of diphtheria consists in specific immunization.

Passive immunization by injection of antitoxin has never been used to a very large extent in this country compared with the Continent and the United States for protecting the other members of a family or community in which a case of diphtheria has occurred. The immunity which injection of antitoxin confers though immediate, is only of short duration, being rarely longer than three or four weeks. The method also renders the patient hypersensitive—that is, liable to have an unusually severe reaction when a therapeutic dose is administered in the course of the next few years. It is further said to interfere with the subsequent process of active immunization, because the injected mixture has been rendered too much overneutralized to ensure a response. The substitution of cattle serum for horse serum in prophylaxis, in order to avoid a tendency to anaphylaxis, has been carried out in the Argentine, but in this country, so far as I know, cattle serum is not available.

The prophylactic dose of diphtheria antitoxin is usually 500 units, irrespective of age, and may be given subcutaneously or intramuscularly.

The administration of antitoxin by the mouth, which is still sometimes practised both for prophylactic and therapeutic purposes, is, as I pointed out over twenty-one years ago (1906), absolutely futile, and the attribution of any value to it is due to ignoring the fact that many persons exposed to infection may escape an attack of diphtheria not only among the medical and nursing staffs of large fever hospitals, but also among the more susceptible population of younger persons. A convincing proof of the uselessness of this mode of administration of antitoxin has recently been furnished by the Schick test, a positive reaction being in no way affected after administration of antitoxin by the mouth, while it is immediately rendered negative by subcutaneous injection (Aviragnet, Lereboullet, and Marie Lesne Bontellier, and Longevin). The inefficacy of rectal injection of antitoxin has been proved in the same way (Raymond).

It is generally agreed that prophylactic injection of antitoxin should be confined to children, and that adults should not be so treated, on the grounds that the latter are less susceptible to diphtheria and are more likely to come under treatment early if they do contract the disease, whereas they are more prone to a severe attack of serious sickness.

In hospitals and well-to-do families in private practice where the children can be kept under close observation after exposure to infection passive immunization need not in my opinion, be carried out, though I am well aware that it is the practice in some clinics to administer prophylactic injections on a large scale, with or without a preliminary Schick test, on the occurrence of a single case of diphtheria in a children's ward.

ACTIVE IMMUNIZATION

In contrast with the temporary protection afforded by passive immunization, a more durable and possibly permanent immunity is conferred by active immunization. This method of protection against diphtheria was first introduced in 1913 by von Bebring to whom we are all indebted for diphtheria antitoxin, but it was first used on a large scale by Park and Zingher in the United States and subsequently on the continent of Europe, and last of all in this country, where its progress has been less rapid than elsewhere, but now appears to be steadily gaining ground. The substance used for injection at first consisted of a standardized mixture of toxin and antitoxin in three subcutaneous injections of which were given in doses of 0.5 to 1 c.c., with intervals of a week between each dose. The Schick test was then performed to determine whether immunity had been established or not.

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Cardiff, 1928.

It has recently, however, become the practice to dispense with the preliminary Schick test, especially in public health work, in dealing with children under 6 years of age, owing to the great majority of them being susceptible to diphtheria and an unnecessary prick is thus avoided. On the other hand, in the case of adults, who are more likely to react severely than children to the immunizing injections, a preliminary Schick test is indispensable. This particularly applies to the nursing staffs of fever hospitals, in a large proportion of which it is now the rule to carry out active immunization of the nurses when they join the staff.

Since the introduction of active immunization of newcomers—it was considered unnecessary to apply the method to the older nurses—the incidence of diphtheria among the nurses at my hospital, though it has never been very high, has shown a slight fall. It must be admitted, however, that attacks of diphtheria occasionally do occur in nurses whose Schick reactions were negative either spontaneously or as the result of active immunization. This occurrence is probably due to the fact that nurses in the course of their duties are exposed to massive doses of virulent infection which succeed in breaking down their natural or acquired immunity, whereas other persons with negative Schick reactions, who are exposed to only slight and occasional infection, escape.

In some hospitals active immunization is made as compulsory as vaccination against small-pox, while in others it is optional. I have adopted a halfway plan of making all nurses who object to active immunization call at my office and I have found that the disagreeable prospect of an interview with the medical superintendent usually acts as a deterrent to refusal. In addition to its use in protecting nurses active immunization is also indicated in schools, crèches, orphanages, and other collections of children.

Although no fatal accidents following active immunization have taken place in this country, the local reaction and constitutional disturbance are occasionally sufficiently severe to necessitate the nurse being taken off duty for one or two days. In these circumstances, therefore—namely, occasional failure to protect and possibility of severe reactions—I have hesitated to make active immunization against diphtheria compulsory like vaccination against small-pox, especially as in diphtheria antitoxin we have an infallible remedy which will jugulate the disease if used within the first twenty-four hours, whereas in small-pox there is no treatment, however early it is applied, which will invariably modify its course.

The fatal accidents to which I have alluded have been extraordinarily rare in comparison with the vast number of prophylactic injections given, but have of late acquired an undue prominence. With the exception of the disaster reported by Tsien, Dzen, and Chang, which occurred in China, where the deaths of 5 out of 81 persons injected appear to have been due to a streptococcal contamination of the toxin-antitoxin mixture, the fatalities were caused by diphtheritic intoxication, as at Dallas in Texas,¹ at Baden near Vienna,² and at Moscow.³ Death in such cases occurred within a few days from toxæmia, or two or three weeks later from characteristic diphtheritic paralysis, while cases which recovered had cutaneous necroses at the site of injection or extensive paralysis. In this country, however, as already stated, no fatalities following active immunization have occurred, or at all events have been reported, nor, indeed, is it likely that they will occur in the future, owing to the fact that the toxin in the immunizing mixture has been generally replaced by toxoid—that is, toxin treated with heat and formalin.

Dr W. H. Park, director of the Research Laboratories of the Department of Health, New York City, has combined the test for determining immunity with prophylactic injection as follows, thus doing away with the necessity for a preliminary Schick test. 1 ccm of toxin-antitoxin of the standard degree of incomplete neutrality is injected subcutaneously on the inner side of the arm just above the elbow. On the sixth or seventh day the arm is inspected and those in whom there is no reaction

are given no further injections. Those who show a slight reaction are given a second injection, and those who give a definite reaction are given two injections. Dr R. A. O'Brien, whom I recently consulted about this method, kindly supplied me, about six months ago, with a preparation named D.P.I.M. (diphtheria prophylactic immunizing mixture), in which the Schick test was combined with an immunizing mixture for intradermal use. Although satisfactory results have been obtained on guinea-pigs, our experience of the preparation has not been encouraging. Not only were local reactions more severe, but a smaller number of nurses were immunized after the usual number of injections than when the ordinary immunizing preparation was used.

Some French clinicians, such as Lesne, Marquety, Lemme, and Moumignat, have recently adopted the nasal route in preference to subcutaneous injection for active immunization, and found that it was possible to convert a positive into a negative Schick reaction by instilling into each nostril three or four drops of pure anatoxin (diphtheria toxin deprived of its toxic properties by the combined action of heat and formalin) for eight consecutive days, followed, after an interval of eight days, by another course of equal duration. Anatoxin, therefore, like adrenaline, can be absorbed into the system from the nostrils, and, if the value of this method is confirmed, intranasal instillation may prove more acceptable, especially to those of a pusillanimous disposition, than subcutaneous injections. The only drawback to the method as C. Zoeller and G. Ramon have shown, is the impossibility of being certain how much anatoxin has been absorbed, for some may be expelled from the nostrils or pass down the oesophagus. More anatoxin, therefore, must be used, so that intranasal inoculation is not so economical as subcutaneous injection.

TREATMENT

The treatment of diphtheria may be considered in order of importance, under the three headings of serum therapy, general measures, and local treatment.

Serum Therapy

It is the custom in most of the Metropolitan Asylums Board Hospitals to employ comparatively large doses of antitoxin, 4,000 to 8,000 units being given for mild faucial or nasal cases, 12,000 to 16,000 units for moderate attacks, and 24,000 units, repeated if necessary for severe cases. As regards the route for introduction of antitoxin, unquestionably the best, in my opinion, is the intramuscular, the injection being made on the outer side of the thigh into the body of the vastus externus. The thigh is to be preferred to the gluteal region, not only because there is less risk of injuring important vessels and nerves, but also because the femoral muscles are much more compact and exercise greater pressure on the injected fluid. Intramuscular injection ensures a much more rapid absorption of antitoxin than the subcutaneous method, and is much safer and pleasanter for the patient than intravenous injection, which, as even its most enthusiastic advocates admit, is followed in a large proportion of cases by rigors or shock.

Abscesses at the site of injection, which if proper care be taken should be extremely rare, are less common in my experience than after subcutaneous injection, and usually heal up quite as quickly.

It might seem hardly necessary to give utterance to the commonplace remark that we should be guided by the clinical appearances and not by the bacteriological report in the treatment of a case of sore throat, but I still frequently see cases that have been treated at home for "septic tonsillitis" owing to a single negative swab which has probably not been taken with sufficient care, and are sent to hospital only to die when the clinical evidence of diphtheria becomes too glaringly obvious.

While fully convinced of the importance of the early administration of antitoxin—I have never seen a death from diphtheria or severe paralysis when antitoxin had been given on the first day of disease—I cannot too strongly denounce the doctrine which appears still to be widely taught, especially by throat specialists, that antitoxin is of no value after the fifth day of disease. If this doctrine

¹ J. Amer. Med. Assoc. 1919 lxxiii 1778.
² Kl. Woch. 1925 lv 169.
³ Bull. Inst. Pasteur 1927 xxv 312.

were consistently acted upon the mortality of diphtheria would be considerably higher than it is at present.

In a series of 3,000 diphtherial patients of whom I was in charge throughout their illnesses no fewer than 539, or 17.9 per cent, were admitted after the fifth day. With the exception of 12 very mild cases all the patients in whom membrane was present in the throat or nose received antitoxin. Of these 18 died—a mortality of only 5.5 per cent. As the great majority of these cases were in children, and every form of the disease was represented, the low mortality cannot be attributed to the patients being adults, among whom the death rate from diphtheria is usually low, nor to the mildness of the attack. In view of the fact that in the pre-antitoxin era, even when cases were brought under treatment at the very onset of the disease, the mortality was never less than 23.8 per cent, and often rose to 50 per cent or higher, we can only ascribe the low figure of 5.5 per cent to the use of antitoxin.

It is important to realize, as I pointed out many years ago (1907), that the evolution of diphtheria may be rapid and malignant, so that even enormous doses of antitoxin given on the second day of disease may not avert a fatal issue or comparatively slow and benign, so that the disease, which may have been in progress for a week, yields rapidly to a small dose of antitoxin without any sequel.

We should, therefore, be guided by clinical rather than chronological considerations in our treatment of diphtheria—the presence of membrane in the throat, nose, or elsewhere, however late in the disease, being an indication for serotherapy. I have seen so many late cases in which my original gloomy prognosis was happily falsified that I am inclined to say of diphtheria as Ricord did of syphilis: "As regards recovery, everything is possible, sometimes even the impossible."

The chief advance in recent times in the treatment of diphtheria is the use of a refined or concentrated serum whereby the incidence of rashes and other unpleasant sequels is reduced to a minimum. Since our employment of this serum at the Western Hospital in April, 1927, the frequency of serum sickness has fallen from about 60 to under 30 per cent. The only serum phenomenon now seen is urticaria, which is often limited to the site of injection, lasts only for a few hours, and is not accompanied by rise of temperature or constitutional disturbance. With the raw or unconcentrated serum not only was urticaria much more frequent but in about 12 to 15 per cent of the cases injected a secondary rash, at first amorphous or morbilliform and later circinate, appeared, usually attended by a more or less considerable rise of temperature, pains in the joints or muscles, and a varying degree of cervical adenitis. In a small percentage of cases there was a return of the sore throat, manifested by patches on the tonsils to which I gave the name many years ago (1906) of "angina redux." Since the refined serum has been employed I have not seen any of these manifestations of the secondary syndrome.

The introduction of this refined serum is a great boon to the patient. Though somewhat more expensive than the unconcentrated antitoxin it is well worth the additional cost. In previous times it not infrequently happened that the patients, especially adults, suffered as much or even more from serum sickness than from an attack of diphtheria.

General Treatment

Next to early administration of antitoxin the most important principle in the treatment of diphtheria is the enforcement of rest for a period proportionate to the severity of the initial angina. In mild cases rest in bed for the greater part of the time in the recumbent position should continue for three weeks, while in severe cases the period of recumbency should be extended to six weeks, or more if any paralysis is present.

It is doubtful if any drug has the power to modify favourably the course of the disease, though I am inclined to think that adrenaline may be of value in forestalling or combating the suprarenal insufficiency which plays an important part in the syndrome known as cardiac paralysis.

Alcohol was long regarded as an indispensable drug in the treatment of diphtheria and as such was advocated by such well known authorities as Jacoby of New York

and Ker of Edinburgh, as well as by many lesser luminaries in the medical firmament. Even now it is still used on a large scale in the acute stage or in convalescence by some pyretologists, who harbour the delusion that alcohol is a cardiac stimulant or is otherwise indispensable.

When I was appointed medical superintendent at the Western Hospital I found that the annual consumption of brandy in the previous year (1925) had been 2,589 oz., most of which had been employed in the treatment of diphtheria. I at once set to work to convince my colleagues that alcohol, so far from being of any value in the disease, was liable to increase the myocardial degeneration initiated by the diphtheritic poison.

The result of my anti-alcoholic campaign was that the amount of brandy ordered on the diet sheets fell from an average of about 30 or daily to nil without any ill effects, the diphtheria mortality being lower in 1926 (4.53 per cent) than in the previous year (8.54 per cent), while in 1927, when no alcohol at all was used in the treatment of the disease, the diphtheria mortality (3.01 per cent) was lower than in any of the other Metropolitan Asylums Board hospitals, although the type of disease has remained the same during the last three years.

Time does not permit me to deal with the relative merits of tracheotomy and intubation, or to discuss the management of diphtheritic paralysis, about which there is little new to be said. A few remarks, however, may be made in conclusion, as regards the local treatment of diphtheria. Since the introduction of antitoxin local treatment in the form of syringing, spraying or gargling has occupied a very secondary position in treatment. In my series of 3,000 cases I have employed local treatment in only 364 cases, or 12.13 per cent. Most of these patients were older children or adults, who welcome any form of local treatment, which young children as a rule resist.

From comparative observations I have found that the average period for the throat to become clean after injection of antitoxin is practically the same, whether local treatment is employed or not.

RARE COMPLICATIONS OF ACUTE APPENDICITIS*

BY

R. KNIGHTLY SMITH, M.R.C.S., L.R.C.P.,
 HOUSE SURGEON, KIDDERMINSTER AND DISTRICT COUNCIL HOSPITAL.

THE following cases of appendicitis are of considerable interest and seem to deserve recording. They are noteworthy on account of their extreme rarity and because they present many unusual features, which increased the difficulty of pre-operative diagnosis.

CASE I—Acute Appendicitis Accompanying a Perforated Duodenal Ulcer.

A man aged 35 was admitted to hospital on August 21st 1927 complaining of abdominal pain and vomiting.
 History.—Nine hours before admission the patient was seized with sudden pain in the upper part of the abdomen. The pain started slightly to the right of the midline and passed down the right side of the abdomen into the right iliac fossa. It was sufficiently severe to double him up and its onset was accompanied by vomiting. The patient had suffered off and on for eighteen years with pain in the upper abdomen coming on two hours after food and lasting for a variable period. The pain was relieved by taking food. He gave no history of vomiting and had never been jaundiced. The bowels and micturition had always been normal.

* From a paper read to the Kidderminster Medical Society, April 20th 1928.

Examination—On admission the patient looked ill, the mucous membranes were slightly cyanosed, the tongue was dry and furred. Temperature 98° F, pulse 110, respirations 24. The pupils were semi-dilated, and reacted normally to light and accommodation. Nothing abnormal was found in the examination of the chest. The abdomen did not move on respiration, and there appeared to be some fullness in the right iliac fossa. There was tenderness and rigidity all over the abdomen which was most marked in the right iliac fossa. There was dullness in the flanks and in the right iliac fossa. Liver dullness was present. Rectal examination disclosed nothing abnormal.

Operation—An immediate exploratory laparotomy was performed, a two-inch incision being made in the right iliac fossa. On opening the peritoneal cavity much turbid but odourless fluid exuded. The appendix was brought into the wound, and was found to be swollen, the whole of the outer coat was markedly inflamed and there were many recent adhesions around it. The appendix was removed in the usual manner. On further examination it was discovered that the lumen was filled with a thick blood stained fluid which had a fetid odour. On washing away the fluid it was seen that the mucous membrane of the appendix was altered in its distal half, and that this region was studded with multiple large thrombi. No perforation was present. It was not thought that the condition of the appendix was sufficient to account for the large amount of free turbid fluid in the peritoneal cavity. A second right paramedian incision was made in the upper abdomen when it was discovered that turbid fluid was oozing from a small punched-out perforation one-eighth of an inch in diameter situated on the superior surface of the duodenum just distal to the pylorus. An indurated area about one inch in diameter was palpated surrounding the perforation. The perforation was closed by a purse-string suture and then sewn over. The gall bladder was found to contain a hard mass but no operation on it was performed. The upper incision was partially closed with tubal drainage down to the region of the perforation. A drainage tube was passed through the incision in the right iliac fossa down into the pelvis and the rest of the wound was closed.

The patient made an uninterrupted recovery and was discharged from hospital three weeks later with his wounds healed. He was advised to return to hospital in one month for exploration of the gall bladder.

He was readmitted one month later and cholecystostomy was performed when the gall bladder was found to contain a mass of clay like material but there were no definitely formed stones. The cystic duct was full of the same material which was evacuated with a gall bladder spoon. A tube was inserted into the gall bladder and secured with a purse string suture. The gall bladder was then sewn to the posterior aspect of the anterior abdominal wall and the rest of the wound was closed. There was slight bile drainage for four weeks after which the patient was discharged from hospital quite well with his wound healed.

Comment

The association between duodenal ulcer and chronic appendicitis has long been well recognized, but perforation in the former and acute inflammation in the latter occurring at the same time is very unusual, although it is not infrequently found that some degree of peri-appendicitis accompanies a perforated ulcer.

Where two conditions are present at the same time it is always wise to associate them rather than to make two separate diagnoses, nevertheless, in this case the possibility must be borne in mind that the duodenal ulcer had been present for a number of years, and had in its intimate connexion with the acute inflammation in the appendix. On the other hand, it may well be that there had been chronic inflammation in the appendix, which had been superseded by acute inflammation, and that this had caused the onset of an acute process in the ulcer, previously present, which had resulted in perforation, or that the acute process in the appendix was secondary to an acute process in the ulcer.

In this case, although the symptoms pointed to its being one of duodenal perforation rather than acute appendicitis, the onset of pain being in the upper abdomen and there being a long history of indigestion, nevertheless, from the examination of the abdomen, some difficulty in pre-operative diagnosis was presented. The case was further complicated by the additional presence of gall stone sand.

CASE II—An Acute Gangrenous Perforated Appendix in the Sac of a Strangulated Inguinal Hernia

A man, aged 77, was admitted to hospital on January 23rd 1928 complaining of abdominal pain and vomiting.

History—The patient had had bilateral inguinal hernia for forty years. Both herniae had always been easily reducible and had been partially controlled by a truss for many years. Two days before admission he was seized with sudden severe pain in the right groin, the onset of the pain was accompanied by vomiting. The pain and vomiting had persisted and the hernia on the right side had become tender and irreducible. The vomit had been dark brown in colour during the last twenty-four hours before admission. In the course of the previous two days his abdomen had gradually increased in size and he had had

diarrhoea. For the last twenty-four hours he had not passed any flatus. Micturition had always been normal.

Examination—On admission the patient looked ill. His tongue was dry, and covered with a dark brown fur. Temperature 99.6° F, pulse 110, respirations 24. Nothing abnormal was discovered in the examination of the chest. The abdomen was markedly distended but moved on respiration. There was tenderness all over the abdomen but no rigidity, the percussion note was resonant and there was no dullness in the flanks. Bilateral inguinal herniae were present extending down into the scrotum. The skin over the right hernia was reddened in the region of the external abdominal ring. The hernia was very tender on palpation, and the percussion note over it was resonant. No attempt was made to reduce the hernia. By the rectum nothing abnormal was discovered.

Operation—An incision was made over the right hernia, the sac was defined and the cord was separated. A small amount of green turbid fluid escaped on opening the sac which was found to contain the caecum and omentum. The caecum was injected and had recently formed flakes of lymph on its surface. The appendix was in the centre of the sac, the whole of its wall in its distal three-quarters was gangrenous and there was a small perforation about one inch from the distal end. The gut was constricted by the neck of the sac. The cavity was swabbed out and the appendix was removed. The caecum and omentum were returned into the peritoneal cavity. The sac was tied and excised and the wound closed with drainage.

Subsequent History—The patient was treated with enemata and aperients. On January 24th he had a good result from a turpentine enema passing much flatus and formed faeces. His abdomen was less distended and he had not vomited. The following day he had not passed flatus and the abdomen was more distended, he vomited green fluid several times during the day and had clear results from enemata. On January 27th the abdomen was still more distended, he had not passed flatus and had had clear results from enemata. He was vomiting dark brown fluid. The abdomen was not rigid.

Second Operation—Exploratory laparotomy was performed through an incision in the right iliac fossa. On opening the peritoneal cavity it was found that the small intestine and caecum were markedly distended. There was no peritonitis. A band was felt constricting the large intestine just distal to the caecum and the transverse colon and descending colon were collapsed. The constricting band was divided and caecostomy was performed. The wound was closed and the caecostomy was opened, when a slight amount of flatus escaped.

On January 28th the patient had frequent large openings of the bowels by the rectum. The caecostomy had not acted. Two days later he was much weaker. His bowels were well open both by the rectum and by the caecostomy. His abdomen was less distended. He was incontinent of faeces. He died on February 1st.

Comment

In this case the question arises whether the condition was primarily one of acute appendicitis or whether it was secondarily due to strangulation of the appendix. The fact that there were recently formed flakes of lymph in the region of the appendix, and that the organ was perforated, suggests that the condition was primarily one of acute appendicitis rather than a strangulation of the appendix. An unusual feature in this case was the additional presence of a constricting band, which added considerably to the difficulties in pre-operative diagnosis, although, owing to the absence of signs of peritonitis, organic obstruction by a band had been suspected.

CASE III—An Acute Gangrenous Perforated Appendix in the Sac of a Lost Operative Ventral Hernia

A man aged 25 was admitted to hospital on February 1st, 1928, complaining of abdominal pain.

History—Fourteen days before admission the patient had sudden severe pain in the right iliac fossa accompanied by vomiting. The pain had persisted although after the first few hours it had become much less severe and was now merely a dull ache. He had had no further vomiting. He suffered from constipation the bowels being opened with difficulty every two or three days. Micturition was normal. He had been operated upon two years previously for appendix abscess. The abscess was drained but the appendix was not removed. He was advised to return to hospital three months later for removal of the appendix, but he failed to do so.

Examination—On admission the patient looked ill. His tongue was moist and slightly furred. Temperature 98.4° F, pulse 82, respirations 20. Nothing abnormal was discovered in the examination of the chest. There was a ventral hernia about four inches in diameter in the region of the old appendix abscess scar, the skin over the hernia was normal. The abdomen moved well on respiration and there was no distension, tenderness or rigidity in any part. A hard mass three inches by two inches was felt in the centre of the ventral hernia, the mass was not tender and there was no gurgling on palpation. The percussion note over it was dull. Nothing abnormal was discovered on rectal examination.

Operation—An incision was made over the ventral hernia and the sac was defined. It was thin walled and lobulated and contained a mass of omentum in the centre of which was a gangrenous perforated appendix surrounded by four ounces of pus. The appendix surrounded by the omentum and pus was wrapped in a gauze swab and removed. The scar tissue of the old wound was excised, and the fasciae and muscle were drawn

together with mattress sutures, the wound being partially closed with tubal drainage.

The patient made an uninterrupted recovery and was discharged from hospital five weeks later quite well and with his wound healed.

Comment

This was an undoubted case of a recurrent attack of acute appendicitis, and merely gives additional evidence to prove the advisability of not operating on these cases.

It is interesting to note that in this particular case the patient himself alone was to blame.

An unusual feature was that the recurrent attack occurred inside the sac of a post-operative ventral hernia, and this complication helped to cause some difficulty in pre-operative diagnosis.

The absence of tenderness over the hernial sac and of rise of temperature pointed to the condition being one of incarcerated hernia rather than to its being an acute gangrenous perforated appendix, with the presence of pus.

I am indebted to Mr Lionel Stretton for permission to publish these cases.

SYNDACTYLISM IN FOUR GENERATIONS

BY

DAVID PERKOFF M.R.C.S., L.R.C.P.

RECENTLY I have treated the rare condition of syndactylism in three generations of one family, and a member of the fourth generation, now deceased, was definitely known to have this deformity. These cases are submitted as an interesting problem on the subject of heredity.

Syndactylism as the name implies, is a condition in which there are webbed fingers with a more or less close union of contiguous digits. Three main varieties may be distinguished: (1) union by skin only, (2) union by skin and fibrous tissue, (3) a condition when the bones are more or less fused together.¹

FIG 1

Photographs of the hands of the grandmother mentioned in the text. Fig. 1 shows the backs of the hands and Fig. 2 and 3 the palms. The rudimentary separation of the thumb of the right hand is seen in Fig. 2.

FIG 2

FIG 3

Another variety, the "lattice type" exists in which the bases of the fingers are separated, but distally they are united. Such cases afford a strong reason for assuming a mechanical origin. It is possible that the fingers have developed and then later, for some reason, they have been subjected to pressure and adhesion has taken place. This assumption is strengthened when it is noticed that sometimes at the point of union the last phalanx of one finger overlaps the other. It is usually the inner side of the hand which is affected, and the fusion of the thumb and index finger is a rarity. Messrs Roucaurol and Klausner have however reported cases of this rare type.

CAUSATION

The leading theories of causation according to Roucaurol and other authorities are:

- 1 Lesions of the foetal nervous system (Cernik)
- 2 External pressure and traumatism during pregnancy (Crusellier)
- 3 Embryonic amniotic adhesion (Lommelongue)
- 4 Amniotic loops or bridles (Doreste)
- 5 Reversion to early conditions (Darwin)
- 6 Osler thinks it occurs more frequently in children of epileptic appearance.

Edward states that it is a stigma of degeneration occurring in persons of weakened intellect.

Goldman asserts that syndactylism may be regarded as an arrest of development since during foetal life the fingers are bound together for a time by webs of varying extent the thumb almost always remains free and in most instances two fingers only usually the third and fourth are bound together.

Like many foot and hand conditions, syndactylism is markedly hereditary.² Lucet³ mentions a syndactylic

family of thirty-nine members fourteen of whom had the deformity. Sverdrup⁴ describes it in six generations of a Norwegian family. Lpstein reports it occurring in five generations, transmission occurring in male and female.

A valuable monograph⁵ by Messrs Lewis and Embleton gives a very exhaustive investigation of the members of one family in which there is a record of forty-four members having deformities of the hand and foot. Douglas P. Murphy⁶ has made a study of the deformity in five successive generations.

In the Johns Hopkins Hospital Bulletin⁷ of 1927 a case was reported of combined acrocephaly and syndactylism occurring in mother and daughter. The two cases reported support the view expressed by Park and Powers that the combined malformations are evidences of germ-plasm defects rather than the results of externally operating causes.

CASES DESCRIBED

I have been able to obtain full details from the living members of this family which I am about to describe. Unfortunately I have not been able to trace the great-grandmother, but she was definitely known to have deformed hands.

The grandmother aged 65 has syndactylism of both hands and has never undergone operation for the deformity. From the accompanying photograph (Fig. 1) it will be seen that there is complete syndactylism of the left hand with that rare occurrence the fusion of the thumb and index finger. The dorsal surface of the hand is very misshapen on the ulnar side with marked bosses over the interphalangeal joints. The nails are very large and there is a slight division in them showing attempts at separate nail formation. The right hand has complete syndactylism but the thumb is separated in a rudimentary form (Fig. 2). There are less fingernails on the right hand and they are marked by grooves showing attempts at separation. In spite of these deformities she is quite dexterous and can manage all simple household work.

The mother Mrs. X aged 33, has syndactylism of both hands. She came under the care of Mr. Openshaw at the London Hospital in 1897 when she was 3 years old and was successfully operated upon. She has one sister who is similarly affected and three other sisters who are quite normal in this respect. There was also a stillborn brother who was said to have had the prevalent defect. Originally in both hands the fingers were enclosed in a web of skin.

Both Mrs. X and her sister had six sets of digital bones on the right but the mother and one of the other children's sixth set were more complete than Mrs. X's whose sixth finger consisted of a small rudimentary process of the other side of the hand. The digital bones otherwise appeared quite complete and the movement suggested that the muscles were normally attached. At the distal part of the web of skin was a ridge of nail-like substance representing the normal nails. The thumb was partially separate on each hand.

In a period of three years fifteen operations were performed and as a result she now has five very useful and completely functioning digits on each hand. She is able to wear a wedding

ring can do anything with the fingers, and is able to write well. She has a slight nasal deformity—a flattening of the terminal cartilage. Her mother has the same defect in a slight degree. The feet of both are quite normal.

The child, aged 6, was treated at the London Hospital by Mr. Souttar when she was 15 months old. She had complete syndactyly of both hands. The x-ray report showed that the right hand had six metacarpal bones and the left hand had five metacarpals. She exhibited polydactylism in both feet and had a supernumerary digit on the tibial side of the big toe on each foot.

She was operated on in 1922 and the hands were divided down the centre along an incomplete division which was present. There were three fingers on each side of the division. The completed hand was of the 'lobster claw' variety.

In a further operation the supernumerary digits of the feet were removed. She has had no further operations, but her hands in their present form are quite useful. She exhibits the nasal deformity of the mother.

It will be noticed in these interesting series that the stigma has continually appeared in females, although it is known that one stillborn male had the defect.

MEDICAL, SURGICAL, OBSTETRICAL.

ANTISTREPTOCOCCAL SERUM FOR INSECT BITES

THE British Isles are remarkably free from dangerous biting insects, but at this time of the year, as noted in the lay press, they take their small toll of life. The insignificant origin makes this all the more distressing. The course taken by these cases is that, immediately following the bite, there is acute inflammation, due either to poison in the insect's mouth or to its excreta deposited there. This inflammation subsides, but after a day or two lymphangitis or erysipelas develops, and the patient dies of septicaemia. The two following cases are reported to show the remarkable effect of polyvalent antistreptococcal serum. I have not heard previously of the use of this serum in such cases.

Case 1.—A woman while gathering raspberries, was bitten by a grey fly. She saw me ten minutes later when the finger was twice its normal size, red and pulsating violently. I advised a tight bandage for an hour, fomentation, and radiant heat. The following morning the finger seemed to be much better, but twelve hours later it became intensely painful. Lymphangitis was present and spreading on to the dorsum of the hand, and the patient felt ill. An injection of 25 ccm. of polyvalent antistreptococcal serum was given into the buttock with the result that in three hours the lymphangitis had almost gone and the pain was much less. The bite discharged for three days, after which the patient had no further trouble.

Case 2.—A child aged 5 with a similar history was given 5 ccm. of serum, in one hour the lymphangitis which had extended almost up to the elbow was arrested and it had disappeared on the following day.

Being interested in infected insect bites as a cause of non-filarial elephantiasis, I made inquiries as to what insects found in this country were liable to cause infection. It appears that almost all the fatal bites are due to the stable-fly, *Stomoxys*, the mandibles of which are heavily infected with bacteria, especially streptococci, from contact with manure and stable refuse. The house-fly is neither a blood sucker nor a biter. Occasionally infection may follow mosquito stings, but it is rarely that any bite in this country causes death, except the *Stomoxys*.

A. P. BERTWISTLE, F.R.C.S. (Ld)

COMPLETE RUPTURE OF JEJUNUM WITHOUT EXTERNAL WOUND

THE interesting case of complete transverse rupture of the jejunum without external wound reported by Dr. J. R. Armstrong in the *British Medical Journal* of June 23rd (p. 1064) recalls a very similar case which occurred in my hospital practice in Hankow, China, about four years ago and which was not recorded at the time.

A Chinese postman was carrying mail bags on his back a launch when he fell between the launch and pontoon to which it was moored, and his abdomen was nipped between the two. He was brought straight to hospital, and I saw him soon afterwards. There was no injury to the skin of the abdomen, but he complained of very severe pain in the epigastrium, and the abdominal wall was very rigid. These symptoms, together with the history, made me advise operation at once and fortunately there was no delay over consulting relatives who might or might not consent.

The jejunum was found completely severed transversely in one place, but no other viscus was injured. The peritoneum contained some blood but no escaped bowel contents. A little trimming of the bruised ends was all that was needed before doing an end-to-end suture.

The operation gave speedy relief to his pain, there was little or no vomiting, and convalescence was uneventful.

This satisfactory result I attributed to the fact that he was a young and healthy man, that there was little soiling of the peritoneum with bowel contents, and that operation was performed early, within less than three hours of the accident.

A CASE OF HERMAPHRODISM

Records of individuals of doubtful sex have been unearthed at U. of the Chaldees, and men of old believed in true hermaphroditism, but no case of the efficient formation and discharge of both sperm and ova by the same individual is known. In fact, only three or four cases of undoubted "true" anatomical hermaphroditism are accepted, and in these both partners were not perfectly developed. True physiological hermaphroditism is probably impossible. It is better, therefore, to use the word "hermaphrodite" as meaning simply an individual whose sex is doubtful. No legal definition of sex exists, and it is often impossible to say to which sex an individual of this kind should be assigned.

Such extraordinary advances have been made already in the present century in our knowledge of the meaning of sex and its determination—and so many experiments are now being made in grafting and transplantation and endocrine medication—that the subject is of greater interest than ever. So seldom, however, have human abnormalities come to operation or to post-mortem examination that our knowledge is still very scanty and our textbooks imperfect, and it seems desirable to report the following case:

XY, aged 22, not a twin. Appearance is that of well developed female in all respects but has never menstruated although each month there is malaise and aching in head, back, groins and breasts. Psychically, seems to be typically feminine, is courting. Other members of the family are said to be abnormal. In the left groin is a reducible lump, and pressure on this causes nausea and sometimes vomiting.

Operation for Hernia (November 7th, 1927).—The lump, when exposed, did not look like an ovary but like a testis, with another solid body attached. Vaginal examination was then made, the vagina was roomy but no cervix, uterus or ovary could be felt. Next the abdomen was opened. No ovary tube or uterus could be seen but just inside the right internal abdominal ring there was a lump looking exactly like that exposed in the left inguinal canal. The abdomen was closed. The left ovotestis (?) was removed and radical cure of hernia completed. Convalescence was normal.

Pathological Reports (Clinical Research Association)

Section A is undoubtedly a testis and shows actual though irregular spermatogenesis. The cells of Leydig are also seen.

Section B shows an interlaced fibrous tissue with irregular vessels. We cannot certainly identify the tissue of which it is the stroma.

Section C. There is no recognizable ovarian tissue and the organ judging by its stroma is more probably a testis. But no genital epithelium of either type is seen.

The specimen was sent to the Royal College of Surgeons, and Sir Arthur Keith with his usual enthusiasm and kindness, had further sections examined without finding any definite ova or Graafian follicles but the areas of fibrous stroma seem to me to be comparable to ovarian tissue.

Human hermaphrodites, like "XY," are usually born singly and are, therefore, less analogous to the well known "free-martin" than to sexually abnormal goats and pigs—where an ovotestis is not unusual and there is a strong hereditary element. The free-martin is externally female, but no sperms are formed by the testes, and it is always sterile and so there cannot be any heredity. Fusion of the chorions of the twin embryos allows mixing of the bloods, so that the testicular hormone from the male twin, being secreted earlier, reaches the female twin and transforms its

ovaries into testes before the ovarian hormone has developed. Fusion of chorions has never been found in the pig. Sexually abnormal goats have been born singly, and certain boars continually sire sexually abnormal offspring.

Females possess male characters in a latent condition and transmit them to their descendants, and it is known—from "freaks of Nature" and from experiments—that individuals of either sex can develop under special conditions, into individuals of the opposite sex. For instance, the healthy ovary of a hen may become converted by disease into a functional testis and the same individual, after acting as a mother, may become the father of offspring—a change of secondary sexual characters (comb, plumage, spurs) accompanying.

Although the sex of the early embryo is determined by the sex chromosomes, the sex hormones—in mammals—very soon prevail and assume entire control. So that in the case of "XY," whilst the organ removed is certainly a testis and is not proved to be an ovi-testis, it seems impossible to account for the very well marked secondary female characters, unless at some period an ovarian hormone circulated. Was it not formerly an ovi-testis, even if it is not such now? If it is, this case is one of "true" anatomical hermaphroditism (so-called) and to be added to the three or four which are all that the best authorities will accept.

Another interesting problem for discussion would be the advice to be given as regards the bringing up of hermaphrodites. Most British authorities following Lawson Tait, advise that they should be treated as males. But in such a case as that of "XY," and remembering that the habits, feelings, and desires depend chiefly on the surroundings of early life, it seems better to agree with Blair Bell and let the anatomy of the external genitals decide. Anyhow "XY" has been left in ignorance of her most unhappy fate.

HAROLD HARTLEY, M.D. Lond., F.R.C.S. Eng.,
Surgeon to the North Staffordshire Royal Infirmary

Rebuefus.

THE FILTERABLE VIRUSES

THE book on the *Filterable Viruses*¹ which has recently appeared under the general editorship of Dr. T. M. Rivers of the Rockefeller Institute is an attempt to present in a systematic manner some of the chief problems encountered in this field of work. Each of the ten chapters of which the book is composed is written by a different author, the man selected being one who has given particular and practical attention to the subject on which he writes. The first chapter, by Dr. Rivers himself, is a review of some general aspects of the filterable viruses. This is followed by chapters on filters and filtration by Stuart Mudd on tissue cultures by Carrel, and on the intracellular pathology of virus diseases by Cowdry. Virus disease of man as exemplified by poliomyelitis is dealt with by Amos and of mammals as exemplified by foot-and-mouth disease and vesicular stomatitis by Olitsky. Virus disease of fowls as instanced by fowl pox is in the hands of Goodpastor and virus diseases of insects and of plants respectively are dealt with by Glaser and by Kunkel. Finally the subject of virus diseases of bacteria in the sense of bacteriophage is reviewed by Bronfenbrener. A full list of references is attached to each article.

So far as we are aware this is the first systematic treatise on the subject of the filterable viruses to appear in the English language in book form. For that reason and also because of the high standard maintained throughout and of the wide perspective that it offers this book is a timely and valuable contribution to progress. The general review by Dr. Rivers himself is particularly to be commended, not merely because of its careful and critical air but also because of its philosophic and constructive outlook.

¹ *Filterable Viruses*. Edited by Thomas M. Rivers. London: Baillière Tindall and Cox, 1958. (Roy. 8vo pp. ix + 423. 26 figures, 15 plates, 34s. net.)

Doubtless in future editions more space will be allotted to the serological side of these infections, which recent work in this country and elsewhere has brought into prominence.

DISEASES OF THE ALIMENTARY TRACT

THE publication of Dr. MARTIN REHFUSS's book, *The Diagnosis and Treatment of Diseases of the Stomach*,² marks an important event in the history of gastro-enterology. The last twenty years have witnessed the development of radiological and biochemical methods which have given much greater precision to the diagnosis of stomach diseases. The pathology and treatment of gastric disorders have been placed upon a sounder basis because of the recorded experience of individual surgeons and physicians and the accurate statistics of hospitals. It is fortunate that a physician who has himself made important contributions to this branch of medicine should have found opportunity to become the historian and exponent of the science and practice of his own specialty. For this is what Dr. Rehfuß has achieved—a book which is both a history and an exposition. These two qualities are not apparent in the general arrangement of the work but the reader becomes conscious of them in the detail of almost every chapter. Dr. Rehfuß says that he wrote the book in the manner in which the subject appealed to him and that he aimed at a practical volume devoted to the consideration of everyday problems in diseases of the stomach and digestive tract. The book is divided into three parts but it is not easy to find a title for each of these divisions which will cover their contents. The first might be described as an introduction to practical gastro-enterology and includes chapters on anatomy, physiology, gastric analysis, radiology and gastroscopy. The second section is a systematic survey of each variety of stomach disease. The third section is devoted to a consideration of gastric symptoms caused by diseases of other organs of the body and to diet. The book contains 519 illustrations, many of them in colour. The author says in his introduction "my excuse for the volume is to put forth in book form my own conception of the subject, embodying all those important communications from the most diverse sources and by many authors which seemed essential to the subject." He has achieved his object with unusual lucidity and distinction and there is no need to speak of an excuse for such a notable service to medicine.

Dr. BASSLER's textbook entitled *Diseases of the Intestines*³ and now in its third edition, comprises a survey of diseases of the liver, gall-bladder, pancreas, and lower alimentary tract. The first question that is likely to be asked about such a book is, What information does it contain which is not to be found in the larger textbooks of general medicine? The justification for a special book of this sort lies in the fact that more space can be given to diagnostic methods, particularly laboratory and x-ray examinations and in the longer account of recent experimental work. We do not notice in Dr. Bassler's volume much about pathology or treatment that is not adequately described in the type of general textbook to which we have referred, but diagnostic methods are certainly considered with much more detail than can be accorded elsewhere. It would have been of advantage to the reader if the author had more frequently given the result of his experience with some of these tests. The book is generously illustrated but some of the reproductions of sections and pictures of bacteria are not of much value. For instance the coloured plates representing the microscopic appearances of stained films in different types of intestinal intoxication are likely to be misleading if taken too literally. The almost complete neglect of references is a grave defect in a large work which professes to offer more guidance than a student's textbook and will frequently occasion disappointment when this volume is consulted.

² *Diagnosis and Treatment of Diseases of the Stomach*. By Martin Rehfuß. M.D. Philadelphia and London: W. B. Saunders Company, 1957. (6 x 9½ pp. 125. 519 illustrations, 65s. net.)

³ *Diseases of the Intestines* including the Liver, Gall-bladder, Pancreas and Lower Alimentary Tract. By Anthony Bassler, M.D., F.A.C.P. Third edition revised and enlarged. Philadelphia: F. A. Davis Company, 1958. (Med. 8vo pp. xx + 805. 199 figures, 78 plates, 10 dollars net.)

THE CARDIAC MECHANISM

In a book on the mechanism of the heart and its anomalies Dr GÉRAUDEL of Paris describes the subject from a novel point of view, which he has already expressed in several publications. He is discontented with what he calls the "classie" theory of the mechanism of the heart beat, the origin of the excitation wave in the sino-auricular node and its spread through the chambers of the heart in orderly sequence. He believes that the intimate correlation of auricle and ventricle is illusory, that in reality the sino-auricular and the auricular-ventricular nodes are entirely independent centres initiating their own rhythms, that in health these rhythms are in equilibrium, and this equilibrium masks their independence, which is revealed by disease. To the special centres he applies the term

"cardio-neuteurs", the S-A node he calls the 'atrio-neuteur', and the A-V node and its prolongations the "ventriculo-neuteur". Each has its own blood supply, and the normal working of the heart depends on the maintenance of normal circulation through the cardio-neuteurs. Disturbances of circulation in one or other, or both, of these territories produce abnormalities in the cardiac mechanism, ischaemia produces slowing, while hyperaemia increases activity. In accordance with this conception Dr Géraudel applies a new terminology to the various disturbances met with clinically—for example, 'prio-systoles' for premature beats and 'hypertachyrythmie auriculaire' for auricular fibrillation.

The first 130 odd pages are given to an account of the special anatomy and physiology of the heart, of the electro-cardiograph, its method of use, and the electro-cardiogram and its normal variations. The remaining 150 pages contain descriptions of the anomalies of cardiac mechanism as recorded by the electro-cardiograph. To these descriptions the author adds the classic and then his personal explanation so that the reader may choose. The choice is not difficult, for, when the volume is examined for evidence in support of his conception little is found. Apparently almost the sole evidence is the finding of obstruction in the artery supplying the 'ventriculo-neuteur' in three cases of heart-block, and of the artery supplying the 'atrio-neuteur' in a case of nodal rhythm.

While it may be admitted, on the one hand, that anomalies of rhythm may be caused through circulatory disturbances, and, on the other, that the classic explanation of the anomalies is not always satisfactory, yet, until Dr Géraudel produces for his views as substantial a body of evidence as there is for the classic theory, his work can hardly be regarded, in the words of the preface, as marking an epoch in the history of cardiology.

LETHAL SOCIAL CUSTOMS

THE disastrous hygienic consequences of certain social customs in India were brought into prominent notice by the controversy that followed the appearance of Miss Mayo's book, *Mother India*. Most persons probably were less impressed by the inaccuracies that were charged against the author than by the number of her charges that were tacitly admitted by her adversaries. Those of our readers who followed this discussion may be glad to hear of a little volume, *The Purdah System and its Effect on Motherhood*, lately published by Dr KATHLEEN VAUGHAN. The status of the two books mentioned is very different, for *Mother India* might be described as the impressions of a tourist, while Dr Vaughan records certain salient facts observed during her work as superintendent of the Zenana at Srinagar Kashmir. It is distressing to learn from this authoritative source that the evils of the purdah system were, if anything, understated by Miss Mayo.

The valley of Kashmir has an altitude of 5,000 feet, and is on the same latitude as southern Spain. The winter is

severe, but the climate is exceptionally good for the greater part of the year. It would be one of the last places in the world in which to anticipate diseases due to light deficiency. The stupidity of man has however, succeeded in frustrating the beneficence of Nature. Dr Vaughan found that in Kashmir osteomalacia was extremely common among the women of the town, but unknown among the peasant women and the women of the boatman class who worked in the open air, moreover, it was unknown in boys and men. The disease was indeed clearly associated with the purdah system. This system is described as follows (p. 10).

A common history is that of confinement to the house at 8 or 9 years of age, marriage at 10 or 11, menstruation at 12 or 13 and close confinement in the husband's house until after the first child is born in the very high-class families the women hardly leave the house until they die.

The author summarizes her conclusions as follows.

Everything would seem to have been arranged to keep these women in the dark and as light is essential to all life they suffer both in body and mind. Deprived of light their skin ceases to form vitamin D from ergosterol their calcium metabolism is interfered with their bones become soft the pelvis crumples up, and we have the classical picture of osteomalacia with its results in difficult childbirth and too often death of mother and child after days of agony when skilled help is not available. There is no doubt that much trouble in later years at the child-bearing period could be entirely avoided by the provision of light for the child as an infant as a girl as a woman. Everywhere there is sufficient light but they cannot use it. This miserable state of affairs all too common in the East, whereby the woman is to all intents and purposes a prisoner in her own home, leads to gross pelvic deformity rendering the birth of children difficult, and unnecessarily dangerous if not impossible and can be prevented by providing her with light. The conclusions drawn from these observations are open to all but the results of such research have never yet been applied to maternity and infant welfare problems in India. It is necessary to point out to those in authority that the present working of the 'purdah' system, by depriving the girls and women of sunlight, is directly responsible for the production of osteomalacia, gross pelvic deformity, and the deaths of thousands of mothers and children in childbirth annually. No schemes for improving the national health of India can afford to ignore such a state of things which takes toll of the more educated of the people whose lives and work are essential to the preservation of all that is good in an ancient civilization.

The author also quotes authorities to show that osteomalacia is common all over India amongst purdah women, and, in particular, mentions a striking example in Bombay, where the disease is unknown among the Parsees, whose women live open air lives but is common among women of the weaver class, who live in dark rooms devoid of direct sunlight. She makes the further observation that one consequence of the purdah system is to make a child marriage almost necessary if living children are to be obtained.

Doubtless the East has accumulated practical wisdom in the course of a few thousand years and has observed that childbirth is easy at puberty and is not so later on when the pelvis has been deformed by an indoor life and is unyielding. I have seen labour in a Hindu girl of 15 or 16 begin with the foetal head bulging over the pelvic brim and end quite normally without interference provided time was given due no doubt to the moulding of the child's head and the elasticity of the mother's still partly cartilaginous pelvis.

Much has been written against the system of child marriages, but this passage suggests that reform must begin with the modification or abolition of the utterly unhygienic purdah system. The evils produced by the purdah system are of great general interest because there is a tendency to assume the existence of certain laws of social evolution that will prevent the occurrence of utterly injurious and useless social customs. Unfortunately the only limit that natural selection imposes on human folly is that it guarantees the ultimate destruction of any community which sins too deeply against the laws of Nature. Customs which interfere with the production of healthy children are peculiarly injurious from the racial standpoint, and the prolonged existence of the purdah system, with all its dire consequences is a reminder of the extreme slowness of the working of the corrective influences of natural selection.

It is easy for us to realize the ills of the purdah system, but it is well to remember that life in our great cities has been organized with an almost equal disregard of some of the fundamental laws of hygiene. Dr Leonard Hill points this moral forcibly in a short preface he has contributed to Dr Vaughan's book.

Le Mécanisme du Cœur et ses Anomalies. Par Emile Géraudel. Études Anatomiques et Electrocardiographiques. Préface du Professeur Vaquez. Paris: Masson et Cie. 1928. (Sup. roy. 8vo pp. vii + 285. 200 figures. 55 fr.)
Mother India. By Katherine Mayo. London: J. Cape. 1927. (5½ x 8½ in. 391 pp. 6s. 6d. net.)
The Purdah System and its Effect on Motherhood. By Kathleen Olga Vaughan. With a Preface by Leonard Hill, M.D., F.R.S., and an Introduction by H. H. Warrall, A.R.S.M., M.D. Cambridge: Hoffer and Sons Ltd. 1928. (Cr. 8vo pp. xv + 48. 1 plate. 2s. 6d. net.)

Our civilization is also not free from blame. Modern research has shown that rickets is caused by the screening from sunlight of women and children by houses clothes and smoke pollution of cities. With rickets goes the decay of teeth. There is evidence that the whole trouble can be prevented by wise feeding and adequate exposure of the skin to open air and sunshine. So too with tuberculosis through ignorance the nation is to blame for the confinement of women and children in slum tenements, just as Indians and Kashmiris are for the confinement in the purdah. While seeking to reform the purdah custom let us see to it that we prevent disease and deformity occasioned by want of light and air at home. Preventive medicine shows the way to stop all this and a new age may look back with astonishment on the artificial teeth of this generation, and the prevalence of rickets and tuberculosis just as we look with astonishment on the purdah system and its consequences.

CREATININE AND CREATININE

THE most recent addition to that admirable series of monographs on biochemistry, edited by Professor R. H. A. Plimmer and Sir F. G. Hopkins is a volume entitled *Creatine and Creatinine*,¹ by Professor ANDREW HUNTER. Creatinine is quantitatively the most important simple nitrogenous constituent of muscle. Creatinine yields only to urea a similar position of importance in the chemistry of the urine. Chemically the two substances are closely related, their mutual transformations are readily effected and their estimation in biological fluids and tissues is simple. No two substances would seem to have greater claims upon the attention of the student of metabolism, and it is true that no two substances have so held the sustained interest alike of the biochemist, the physiologist, and the clinician. Nevertheless it remains to this day a matter of some uncertainty whether the creatinine of the urine derives from the creatine of the muscle or whether the two substances have independent metabolic histories. More elusive still is the larger problem of the origin of the creatine of the muscle. Interest in these questions is likely to be greatly intensified by evidence which has become available during the past year that creatine is intimately associated with the phenomenon of muscle contraction. The problem of creatine is no longer simply one of nitrogen metabolism. It invades the wider field of carbohydrate metabolism. This is an appropriate time therefore, to take stock of our accumulated knowledge of the chemistry and physiology of creatine and creatinine. The appearance of Professor Hunter's admirable and exhaustive monograph is most timely.

The chemistry of these two substances is first reviewed in full and clear detail. There follows the more difficult assembly of the physiological literature. The author has performed a Herculean task. A bibliography of some eight hundred references to original literature is adequate testimony to this. This field has not only been reconnoitred with industry, but also with great ability and discretion. The assembly of data and arguments in an orderly and judicious review has been entirely successful. The critical faculty which is brought to bear on the various physiological hypotheses is always helpful, never impotent. There can be little recompense to the author of such a monograph other than the knowledge of a difficult task accomplished and the realization of a generous gift to his contemporaries. We should therefore be the more ready to acknowledge our full appreciation of the value of his labour.

NOTES ON BOOKS

Dr. JOSEPH HOLLIS has written a book on *Tuberculous Intoxication*,² in which he refers practically every symptom from which mankind may suffer to latent tuberculosis. His general thesis is that persons with a latent tuberculous focus are hypersensitive to the toxins of the tubercle bacillus that they react to a fresh infection by lysing the bacilli, and that the products or endotoxins thus liberated from the bacilli act on the endocrine glands, and through them produce a severe constitutional reaction. Thus, such symptoms as blushing and other vasomotor disturbances, palpitation, arrhythmia, headache, vertigo, fatigue, restlessness, insomnia, all humour psychoses, nightmares, anorexia, nausea, diarrhoea, constipation, rheumatism, menstrual disorders, chronic skin lesions, and

a host of others all result directly or indirectly from the reaction of the over-sensitive body cells to the toxins of the tubercle bacillus. This hypothesis which is nothing else than Friedberger's anaphylactic theory of infection has practically no evidence in its favour. The so-called evidence that the author brings forward to support it is not worth serious consideration. The book is full of misleading and unproven statements and its perusal will leave the reader wondering at the lack of critical ability displayed by the author.

We have received the third volume of a series on medical radiology,³ prepared by four German writers, a notice of the two previous ones appeared in our issue of December 25th 1925 (p. 1231). The present part covers a large amount of ground and the subjects dealt with include the application of X-rays to diagnosis of conditions of the nose, ears, appendix and ecchymococcal infections of the lungs, the use of diathermy in gynaecology and the influence of light treatment on the skin and on metabolism. The book is well illustrated and contains good indexes and a bibliography.

Few callings we imagine can present more opportunity for unpleasant moments than that of the health visitor who surely must combine the wisdom of the serpent with the ease of handling of the toad. It is well therefore that Miss PHYLIS ARMITAGE, now matron of Lady Northey Home, Nairn, should, out of the fullness of her experience, produce a hand-book *Health Visiting The New Profession*.⁴ So few is it that doubt still seems to exist as to whether the main training should be in social work or in nursing and if the latter, whether the training should be in a general or a children's hospital. To judge however from the space devoted by Miss Armitage to descriptions of maternity and child welfare work and of disease it would seem that among much varied knowledge considerable acquaintance with medicine is necessary in health visitors. Herein lies one of the dangers of the profession for it is easy to imagine an ardent health visitor with a smattering of many sciences getting at variance consciously or unconsciously with a doctor whose opinion does not coincide with Miss Armitage's summaries of the treatment of disease. And the author—very occasionally we admit—lets fall remarks about doctors which are not quite discreet. However she wisely ends by telling the health visitor that she is not appointed for the purpose of posing as an amateur doctor and the medical officer of health under whom the visitor works will doubtless see that this advice is carried out. The author's zeal is shown by the story of her visit to a peer whom she found to be ignorant of his duty to notify the birth of his offspring and whose ignorance was shared by the two distinguished consultants in attendance on the peeress.

The verses written during a period of some forty years by the late Dr. MORRIS F. COCK,⁵ (1856-1924), one time of South Molton, Devon, have been collected by his widow. Written in simple language they touch rather a meditative and pathetic note in dealing with the aspects of life and death that naturally bulk so largely in a doctor's life.

PREPARATIONS AND APPLIANCES

A TWIN SYRINGE FOR USE IN VENEREAL TREATMENT

DR. R. J. HELSBY (Bangor) writes: I have found in doing venereal disease work that when a specimen of blood is to be taken and an injection of neobarsivan to be made at the same time, that the needle frequently moves and perforates the vein when the syringes are being changed. The neobarsivan then permeates

the tissues with disastrous results to the patient. I have had this twin syringe with stopcocks made for me by Messrs. Down Brothers. Both stopcocks are closed and the neobarsivan is mixed in one syringe. The needle with syringe attached is then introduced into the vein and blood is drawn into the empty syringe after opening the stopcock. The stopcock is then closed and the other one opened. The neobarsivan being injected without in any way disturbing the needle.

SATURDAY, AUGUST 25TH, 1928.

RECENT WORK ON THE FILTERABLE VIRUSES

IN spite of the difficulties that beset the experimental investigation of diseases belonging to the virus category, and particularly of those which affect man, knowledge appears to be slowly but steadily advancing in regard to this group of pathogenic agents. How widespread and varied are the activities of these viruses is well brought out in the recently published book by Dr Thomas M. Rivers and his colleagues of the Rockefeller Institute at New York, of which a review appears in our current issue at page 343. In this book the present state of knowledge is set out concerning selected examples of viruses affecting respectively man, other mammals, birds, insects, and plants. Nor is the end necessarily there, for some authorities maintain that the bacteriophage associated with the names of Twort and d'Herelle is nothing else than an instance of an ultra microscopic virus affecting bacteria themselves.

The chief interest to the medical reader, however, of recent work on viruses lies in the light it tends to throw on diseases of man brought about by agencies of this group. Here at present data are perforce limited, and, as the pitfalls are many, caution is particularly necessary. Nevertheless, some encouraging facts are emerging with regard both to prophylaxis and diagnosis. The important question whether it is possible to prevent a disease of the virus category by means of killed virus was apparently solved some years ago when rabies virus killed by phenol was successfully introduced into India for the prevention of hydrophobia, the credit for this advance is due to the pioneer work of Sir David Semple and his colleagues. Parallel but less convincing results in a preventive sense have from time to time been reported experimentally on animals with vaccinia virus inactivated by heat, and more recently by Knoepfelmacher and Stohr in the human subject, it would seem that dosage is here an all important factor and that repeated injections may be necessary for success. Moreover, according to its most recent report (of which an account was given in our issue of August 11th at p. 268) the members of the Foot and Mouth Disease Research Committee appear to have satisfied themselves that protection can be obtained against that disease with the virus after it has been killed by means of formalin.

A further direction in which progress is being made is in the application of serological methods to the diagnosis of virus infections. Experimental evidence has been furnished by a number of observers to the effect that specific antibodies occur regularly in the serum in cases of infection by the viruses of vaccinia and variola. We may note in particular that, according to Mervyn Gordon, in the serum of rabbits suitably prepared against vaccinia, specific antibodies showing an equal affinity for the viruses of vaccinia and of variola can be demonstrated by the complement fixation test and also by the agglutination or precipitin test. Evidence was found that serum prepared by

such means against vaccinia virus could be used for the diagnosis of small pox. It is of special interest in this connexion to observe from the latest report of the Foot and Mouth Disease Research Committee that Professor Ciucu of Bucarest, working in London at the Lister Institute, has succeeded in applying the complement fixation test to the diagnosis of infections by that virus, and that in this way he has been able to distinguish between the two different types of foot-and-mouth virus.

Recent developments, therefore, in the study of the filterable viruses are of considerable promise, and their general tendency is to bring these infectious noise and more into line with those produced by the ordinary pathogenic bacteria.

NOISE.

COMPLAINTS of the noise of London as well as of other cities are not new. Sir Walter Besant wrote of London that 'in the days of Whittington there was no noisier city in the whole world,' a rather bold and sweeping generalization, incapable of proof. Much of that din was inevitable in the carrying on of the handicrafts of the time, but the noises of which we now complain are to a large extent avoidable and might be prevented. At the recent Annual Representative Meeting of the British Medical Association at Cardiff a resolution was moved by the representative of the Edinburgh and Leith Division and carried without discussion, to the effect that the Association should support any measures designed to suppress unnecessary noise, and declaring that any preventable noise between the hours of 11 p.m. and 6 a.m. which is injurious to health should be regarded as a nuisance within the meaning of the Public Health Acts. Dr John Stevens, who moved the resolution, spoke eloquently of the harmful effects of noise and even of silent vibration on the central nervous system, and asked if motor horns could not be less used at night time. The public, he said, were looking to our profession for a pronouncement which might be of service to legislators and local authorities in taking steps to mitigate this evil.

The wording of the Cardiff resolution prudently avoided any reference to specific noises, but everyone who reads it will understand that the framers of it had in mind chiefly the sounds produced by traffic in our streets. Early this month the *Times* opened its columns to a correspondence on the subject of speed and noise, which was begun by a letter from Mr Harold Begbie and continued by various other writers, including Professor William A. Bone, Canon Jocelyn Perkins, Canon Spooner, and Sir Robert Armstrong Jones. Canon Perkins speaks, from personal experience as a former inpatient of Westminster Hospital, of the perpetual hurricane of noise by which that hospital is surrounded and of his sufferings therefrom, in common with other patients. That such sufferings seriously diminish the chances or progress of recovery in many patients is unquestionable and the authority of Sir Robert Armstrong-Jones supports the view that the nervous system must in many cases be injured by these continual and violent stimuli which assault the ears by day and by night. All the correspondents are agreed as to the evil which cries aloud for cure, but the remedies so far proposed are, unfortunately, not very definite or promising.

In discussing this matter it is not possible to separate the question of speed from that of vibration

and noise, for a very large part of the noise and most of the vibration are caused or at least increased by high speed, and even the motor horn nuisance is an indirect result, seeing that it is a rapid approach that calls for a loud warning. Is it too late to undo the *laissez faire* policy which, as one correspondent pointed out, has turned our highways into tracks for high speed and heavy locomotives without any of the safeguards which the railway companies have been forced to provide? The competition is an unfair one, for the railway companies have had to buy the land on which their rails are laid, often at very high prices. They have been put to great expense in providing safeguards for the public, such as bridges, while their rivals have the roads, which they destroy, kept up at the public expense, they pay no rates and provide no safeguards. The lighter private vehicles make less clamour and vibration in running, but their horns make up for any such comparative silence. As for the motor cycle, it is probably for its size the noisiest vehicle that the wit of man has ever invented, and it is no consolation to the sufferer from its successful imitation of a pneumatic drill or loud machine gun, that it often itself puts an end to the racket by slaying its rider or passenger.

It is clear that unless speed on the roads can be effectively regulated—and all attempts made to do so have hitherto notoriously failed—noise will continue. Dr Harvey Hilliard, writing in our issue of August 11th put forward the practical suggestion that the Council of the British Medical Association should promote a bill in Parliament not only to repeal past enactments which permit or enforce noise, but also to make unnecessary noise of all kinds punishable by law. This suggestion was warmly endorsed by Dr William Collier, a past president of the Association, in a letter which we printed last week and further support, by Dr Dan McKenzie and Mr Muirhead Little, will be found in our correspondence columns to day. If the Council, after careful consideration of the great difficulties in the definition of an unnecessary noise and in establishing securely that its effects are noxious sees its way to promote such a bill and to enlist in its support the medical members of Parliament, it will certainly earn the gratitude of many millions of sufferers from the nuisance of speed and noise. This evil is so acute, so diverse and so widespread that nothing short of an Act of Parliament seems likely to abate it. As Canon Spooner has well said, it is a revolution, not a mere change of fashion, through which we are passing.

THE PROBLEM OF MOUNT EVEREST

THE news that an eminent British physiologist has, this summer blazed a new and unsuspected trail to the summit of Mont Blanc reminds us that mountaineering is, historically, a pursuit of scientific men. In the eighteenth and nineteenth centuries mountain climbing was undertaken almost exclusively by men whose interest was to observe the effects upon themselves of exposure to low barometric pressures. Within more recent years climbing has become a sport attracting men of divers callings, but such names as Hingston, Wollaston, Longstaff and Somervell remind us that there are still to be found medical men fit and ready to share in the most hazardous expeditions to high altitudes.

These names, and with them the epic stories of those supreme adventures in mountaineering the several Everest expeditions are brought to mind by

a recent contribution to the *Lancet* on the physiological 'Problem of Mount Everest,' by Dr Argall Campbell. By general consent, the physiological limitation to the attainment of great height resides in the limit of man's adaptability to environments of abnormally low partial pressures of oxygen. At the top of Mount Everest the tension of oxygen is only about 7.5 per cent of an atmosphere, being but a third of that at sea level. What are the physiological effects of low tensions of oxygen? To answer this question the physiologist has taken his laboratory to the mountain. He has also sought to bring the mountain into his laboratory. Closed chambers have been devised in which the subject of experiment is placed and in which the composition of the atmosphere may be controlled at will. Here may be studied the physiological and psychological effects of exposure to any desired oxygen tension under all manner of conditions of rest and activity. Many such studies have been made on man, and this 'armchair mountaineering' has not been without its thrills. But the simulation of such extremes of atmosphere as those obtaining at the summit of Everest are not feasible with man, and Dr Campbell's observations on animals are of special interest on this account. He has made prolonged studies of the effects upon a variety of animals—mice, rats, rabbits, guinea pigs, cats and a monkey—of lengthy sojourn in the decompression chamber. The animals were subjected to a gradual reduction of oxygen tension spreading over several weeks until a partial pressure of 7.5 per cent of an atmosphere was attained. The rabbits, rats, and mice alone survived, and even amongst these groups there were casualties. The most notable pathological change observed was an extreme congestion of the liver and parts of the heart and lungs. This congestion must be attributed to failure in the forward movement of the blood for which the heart is held primarily responsible, though failure of the vasomotor nervous centres or other factors controlling capillary dilatation may be contributory. Dr Campbell concludes that the ability to withstand low tensions of oxygen is conditioned by the ability of the heart muscle to maintain an efficient circulation under the abnormal conditions.

What then is the contribution of these experiments to the problem of Mount Everest? In the first place it is argued that the permanent effects of high altitudes are gradually established as the result of prolonged exposure to lack of oxygen. It therefore seems plausible that the daily inhalation of oxygen for several hours when at the base camps would be preferable to the policy of reserving the oxygen supply for use during the actual climbing at greater heights. It is further suggested that daily subjection to low tensions of oxygen in the decompression chamber might prove to be of valuable assistance in the selection and training of suitable climbers.

The experimental animals of Dr Campbell were not required to undertake arduous exercise, and were not subjected to low temperatures, snow, ice, and chilling winds. Is it to be wondered at that his results give the author no confident grounds for the faith that man will conquer Everest and return? Yet such is the heart of man that we doubt if he will take 'No' for an answer. Indeed, when we recall how near—how tragically near—to success were Irvine and Mallory and how Norton and Somervell reached 28,000 feet and came back, it is difficult to believe that the little more is beyond human reach.

DIPHTHERIA IMMUNIZATION THE QUEENSLAND
FATALITIES

THE chief interest of the report of the Royal Commission which inquired into the Queensland fatalities relates to the finding—after the definite exclusion of diphtherial toxæmia—that the deaths were caused by staphylococci with which the toxin antitoxin prophylactic mixture had been contaminated and which had grown freely in the absence of any antiseptic. The Commission, after calling attention to the absence of *post mortem* and clinical data essential to a full understanding of what happened, critically weighs the evidence available and, though fully realizing that the verdict may cause "surprise and possible controversy," concludes that it could not avoid deciding that the aureus-like staphylococci found in pure culture in the inoculated bottle and in the abscesses of the survivors caused the deaths. The Commission has ably and fully set out the evidence for and against the conclusion which as a body of experienced pathologists, it was at first reluctant to accept. Staphylococci are not generally recognized as liable to cause death within twenty-four hours of inoculation into human beings but we must admit with the Commissioners that "there is not, within our knowledge any previous experience of the results of the subcutaneous injection of large numbers of living staphylococci into young children." They examined the literature and point out that general staphylococcal infections are rarely fatal in less than forty-eight hours, yet in the records of one Brisbane hospital were found three instances of staphylococcal osteomyelitis in children, aged from 2 to 11 years, with death within approximately twenty-four hours. The toxin made by the 'Bundaberg staphylococci' in culture produced skin reactions in some human volunteers in a dilution of 1 in 2,000. There is only one small point in which we have been unable to follow the evidence. The Commission found it "inconceivable that sufficient staphylococcal toxin could be produced *in vitro* in the toxin antitoxin mixture to account for the symptoms," and thinks that the toxin must have been rapidly formed in the tissues of the children injected. We are not quite clear why the possibility of the formation *in vitro* of a staphylococcal toxin lethal to human beings, though not to laboratory animals, was excluded by the Commission. Whatever be the truth on this point, it is fortunate that *Staphylococcus aureus* is readily killed by the usual $\frac{1}{2}$ per cent of phenolic antiseptic contained in vaccines, antitoxins, and prophylactic mixtures issued in most parts of the world. It is worthy of remark that of thirty-two rubber-capped bottles distributed from the same batch of prophylactic as that used in Bundaberg to medical men and recovered by the Commission, 30 per cent were contaminated. Some of the contaminations were considered as "doubtless referable to faulty technique."

SOCIAL PROGRESS IN BERMONDSEY

DR R KING BROWN, who is shortly retiring from the post of medical officer of health for the borough of Bermondsey, has incorporated in his annual report for 1927—the last he will submit—an interesting outline of the growth of the public health department and of the changes noticeable in the social life of the community since he entered the service of the borough in February, 1901. Bermondsey, despite the fact that it touches upon the central area of London, is probably little more than a name to most Londoners, and merely a name to others, but, as Dr King Brown points out, many of the changes which he recalls are the local expressions of national changes. His survey, therefore has a certain general interest, it brings into perspective within a definite area twenty-seven years of social development which has been largely characterized by increasing attention

to public health. When he assumed office the metropolitan boroughs had just been constituted to replace the pre-existing confusion of archaic local government units which traced their descent from ecclesiastical parishes. The borough of Bermondsey succeeded to the territories of the Bermondsey Vestry, the Rotherhithe Vestry, and the St Olave's Board of Works, the three units forming an area with an extensive river front lined with wharves, docks and warehouses, and a hinterland of crowded streets with many factories and workshops. At that time the population of the borough was 130,760 last year it was estimated at 121,000. The reduction has been due, he explains, to the clearance of certain areas for improvements, the replacement of houses by factories, the reduction of population through a decrease in births, and migration to the suburbs—all these being changes characteristic of urban England since the beginning of this century. Both the death rate and the birth rate have fallen by almost half—the death rate from 20.8 in 1901 to 12.9 last year, and the birth rate from 34.2 per 1,000 of population in 1901 to 18.5 last year. The report suggests that the decline in infantile mortality is closely connected with the fall in the birth rate and the consequent reduction in the size of families, another important factor being the education of the mothers—in a general way and also through the agency of the municipal authorities and voluntary bodies. There has been a satisfactory fall in the incidence of infectious diseases as a whole, enteric fever, as elsewhere in Great Britain, has practically disappeared. Dr King Brown considers that the most interesting changes during the period of his office in Bermondsey have been in the general condition of the inhabitants, especially the working classes, and in the public health department itself. He is impressed by the fact that babies and children are much more sensibly clothed, and thinks that this applies also to adults, especially to women. They are, further much "better dressed," and this he attributes to higher wages, smaller families, and the spread of knowledge, especially that relating to health. There has also been a great improvement in the cleanliness, ventilation, and general appearance of the homes. The sobriety of the general population has considerably increased, and here again education seems to the observer to have played the chief part. In tracing the evolution of the health department Dr King Brown explains that before his appointment as the first full-time medical officer for the borough the staff consisted of a part-time medical officer, a chief sanitary inspector, eight district inspectors, and three clerks. There are now five full-time medical officers (two being employed in connexion with the tuberculosis dispensary and two engaged in maternity and child welfare work), a full-time dental surgeon with a part-time assistant, an inspectorate of fourteen, a staff of eight health visitors, nurses and other assistants for dispensary and dental work, and a numerous staff of clerks, etc. The tuberculosis dispensary and the dental clinic both began as voluntary activities, and were taken over by the municipality after the war, their work has in each case expanded considerably since then. In connexion with the treatment of tuberculosis the Bermondsey Council has, since July, 1924 reserved six beds at Dr Rollier's centre at Leysin, while in 1925 light treatment was introduced experimentally at the tuberculosis dispensary, and a specially constructed solarium—one of the first under municipal auspices in England—was opened in 1926. The most recent development has been the inauguration of a systematic health propaganda campaign: this work has been carried out by lectures and the circulation of printed matter, and, more recently by the use of cinema films prepared by the department itself. Dr King Brown notes that the great interest in public health work which has made possible rapid progress in recent years dates from the war, and here, once more, the experience of Bermondsey represents that of the

country as a whole. His survey, based upon observations made over the greater part of his professional life, may, with its record of definite advance, hearten some of those who, being in too intimate contact with the public health system to stand back and see things in perspective, seem "no painful inch to gain."

A JAPANESE REPORT ON SANOCRYSYN

It is a significant fact that in spite of the introduction during the past few years of two or three different chemotherapeutic agents by highly capable investigators, it is the surgical measures of treating pulmonary tuberculosis that are coming more and more into favour. Each year sees an increase in the number of workers who adopt the methods of artificial pneumothorax, thoracoplasty, and pleurectomy for the treatment of the more severe cases of tuberculosis, and a decrease in the number of those who pin their faith to the therapeutic action of drugs. The report¹ just issued by the Sanocrysin Research Committee of Japan does not seem likely to alter this position. After an intensive series of experiments on the action of sanocrysin on the tubercle bacillus *in vitro* and *in vivo*, after a carefully planned series of therapeutic experiments on rats, guinea pigs, rabbits, and calves, and after separate tests on two groups of patients, each lasting about a year, the most they can say in its favour is that it may be regarded as a stimulant in the stationary proliferative type of pulmonary tuberculosis. On the contrary side can be set a long list of grievances. It was found, for example, that it caused but little structural alteration in tubercle bacilli, and that it did not deprive them of their acid fast properties. Its germicidal action was extremely low, even contact for two hours at 40° C with a 1 per cent solution followed by twenty hours at room temperature failed to destroy the bacilli or to render them avirulent to guinea-pigs. No evidence was obtained that it had any lytic action on the bacilli in the animal body or in cultures in the test tube when employed in a 1 per cent solution. Therapeutic experiments with rats and rabbits infected with tuberculosis gave entirely negative results, even though strains of low virulence alone were used, with guinea-pigs there was evidence that the lesions were slightly less extensive than in the controls, but it was doubtful whether this difference could be regarded as significant. Experiments on calves completely failed to disclose any therapeutic action, many animals, in fact, were made very much worse by treatment. The tests on tuberculous patients were similarly disappointing. In the first series of 49 patients who were selected as specially suitable for treatment, only 8 were improved after a year, 9 were stationary, 11 had become worse, 14 were dead, and 7 were lost sight of after discharge. In the second series of 39 selected patients, 15 were improved after a year, 7 were stationary, 11 were worse, and 6 were dead. These figures are necessarily rough, but they indicate clearly enough that no obvious beneficial effect resulted. It is especially significant in this second series that of the 15 "improved" patients two alone ceased to have tubercle bacilli in the sputum. Experiments on Moellgaard's immune serum failed to substantiate the claims made for it by its discoverer. Its agglutinating and precipitating powers were low, its opsonic action was negligible, it had no antituberculin effect and it did not counteract the intoxication following on the injection of sanocrysin. For this reason it was not deemed of sufficient value to use on human patients. Altogether the report of the Japanese workers merely confirms the opinion that the majority of clinicians in this country have adopted—namely, that sanocrysin is not a specific agent in the cure of tuberculosis, that it does not directly destroy the

tubercle bacillus, but that it may perhaps be useful on occasion for stimulating cures of a stationary type which do not respond to the usual sanatorium treatment. On the other hand, it is an intensely toxic substance, and unless used with great care it may cause serious damage to the patient's tissues. Cases with laryngeal and intestinal tuberculosis were found to be especially unsuitable for treatment.

GIUSEPPE FLAJANI

In an article published some months ago Dr Francesco Rampini of Anconaro¹ gave an account of his fellow townsman Giuseppe Flajani, whose name, like that of Graves in this country and of Basedow in France and Germany, is always associated in Italy with exophthalmic goitre. Flajani was born at Anconaro on July 4th, 1739, and, after studies in literature and philosophy at Ascoli, went to Rome in 1758, where he qualified as a physician and surgeon in 1761. Following his natural taste for anatomy, he established an anatomical museum for the use of students in the Ospedale di San Spirito, where he was appointed a surgeon in 1769. Three years later he was elected senior surgeon to the hospital and lecturer on surgical operations, as well as director of the museum to which he added many new specimens, especially vesical calculi which he had removed himself. His reputation now began to spread over Europe, and he was elected a member of the Academies of Naples, Florence, Bologna, Genoa, Sicca, Lucca, Vienna, Mannheim, and Göttingen. Like his contemporary Richard Mead, he collected a valuable library, which contained not only medical and surgical works, but was also rich in literary treasures, rare editions, and valuable manuscripts. In 1777 he published an Italian translation of Pereval Pott's new method of treating dislocations and fractures, with a preface by Francesco Petraglia. In 1786 appeared his work on a new method of dealing with certain surgical diseases—namely, aneurysms of the lower limbs, especially of the popliteal artery, fractures of the clavicle and patella, and the external use of camphor in wounds. In 1798 he began the publication of his collection of surgical observations and reflections, which continued to appear until 1803, and contained, among other subjects, his description of the disease known in Italy as "morbo di Flajani," thus antedating Graves by at least thirty-two years and Basedow by thirty-seven years. In the last year of his life Flajani founded the *Giornale Medico di Roma*, which was continued after his death in 1813, and contained a description of contemporary medical and surgical activities and the scientific development of the Roman school. On this account Flajani may be regarded as one of the pioneers of Italian medical journalism. His posthumous works included one on lithotomy and another on the French disease, which he maintained was not brought over from America, but originated in Europe. His memory is kept alive in his birthplace by his name having been given to one of the streets of Anconaro.

INHALATION ANAESTHESIA

THE furious controversy which at one time raged over the claims of rival discoverers of the use of ether for dental and surgical operations has been dead for some time, but it had a very lingering death. This country had but little concern in that dispute for all the claimants of the honour of introducing ether anaesthesia—Morton, Jackson, and Long—were citizens of the United States, as was Wells, who first used nitrous oxide in dentistry. In our columns on September 10th 1927 (p. 471), Prebendary F. Wayland Joyce recalled the claim of H. H. Hickman to be considered

¹ The Report on Sanocrysin (Moellgaard) Investigation. The Sanocrysin Research Committee of Japan. (Hongo Tokyo, Kyorinsha Printing Company, 1927. (74 x 101) pp. 73. 7 plates.)

² *Bollettino dell'Istituto Storico Italiano dell'arte sanitaria* Nov. 1927, December 1927.

a pioneer in inhalation anaesthesia, which Mr C J S Thompson had previously advanced in the *Journal* of April 13th, 1912 (p 843). In a letter which he has recently addressed to us Prebendary Jayco appeals to us "to do justice in this matter," and to secure for Hickman the credit due to him as the true pioneer in the nineteenth century in anaesthesia by inhalation. As has been already stated in our columns and elsewhere, to Hickman undoubtedly belongs the honour of being the first to experiment with the idea of producing unconsciousness in that way, but the gas used by him in his experiments on animals was carbon dioxide, with which, as we can surely now state a safe and sufficiently deep state of anaesthesia could not be produced. Had Hickman pushed his investigations further, and attempted to render human subjects insensible to pain by such means, it is highly probable that fatalities would have ensued, which would have discredited the method and might even have discouraged subsequent experimenters from attempts to produce anaesthesia by means of ether gases or vapours. It is regrettable that Hickman did not recognize the value of nitrous oxide, with which, as well as carbon dioxide, he experimented. Sir Humphry Davy had long before introduced this gas, and many people had safely inhaled it when diluted with air, but its exhilarating effects when so used masked its possibilities as a true anaesthetic. Discouraged by his ill-success, Hickman seems to have given up his investigations, and ill health and his death at the age of 26 cut off all hope of his making a second start on what might have proved to be a most promising line of research. His tombstone in Bromfield churchyard, Shropshire, has fallen into decay, and we understand that the Section of Anaesthetics of the Royal Society of Medicine is forming a committee to raise funds for its restoration.

LORD HALDANE.

THE death of Viscount Haldane, O M, F R S, will recall to some of our readers that this distinguished statesman, lawyer, and philosopher was a nephew of Sir John Burdon-Sanderson, M.D, F R S, Regius Professor of Medicine at Oxford from 1895 to 1905, and eminent alike as experimental physiologist and pathologist, and a brother of Dr J S Haldane, F R S, of Oxford, many of whose addresses on the physiology of respiration and other subjects have appeared in these pages. Lord Haldane's personal claim to remembrance by our profession rests on his work as Secretary of State for War between 1906 and 1912. In the words of Sir Alfred Keogh, he was one of the two statesmen in latter days (that is, since Lord Herbert of Lea left the War Office in 1860) who understood the Army Medical Department. The Territorial Service set up by Lord Haldane enabled the officers of the R A M C to come into organic union with their brethren of the civilian profession before the outbreak of war.

THE EDUCATIONAL NUMBER 1928

Our next issue, dated September 1st will be the annual Educational Number of the *British Medical Journal*. The familiar sections, giving an outline of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, have been brought up to date, and the information showing the opportunities offered by the various medical schools and other teaching institutions has been corrected by the authorities concerned. These sections the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles of special interest to newly qualified practitioners on such matters as post-graduation study, the public health services, tropical medicine, psychological medicine, and dental surgery. A new article on

women in medicine to-day has been specially contributed, and the editorial notes on some aspects of professional study and practice have been revised and amplified. In the sections dealing with the public services will be found a concise account of the present terms and conditions of service in the R N M S, the R A M C, and the R A F M S, which the Representative Body of the British Medical Association has decided are satisfactory and such as can be commended to the notice of the younger members of our profession. Particulars are also given of the terms laid down for the I M S under the scheme of reorganization. The opening articles for this year's Educational Number have been written by Professor J A Nixon on "The Art and Science of Medicine in Relation to Professional Training," and by Dr R D Gillespie on "The Art of Study: Its Principles and their Application."

MEDICAL SOCIETY OF LONDON

THE next session of the Medical Society of London will open on October 8th, when the annual general meeting will be held at 8 p.m. and Dr J W Carr will deliver his presidential address on medical ambitions and ideals, at 8.30. At the meeting on October 22nd Dr C L Lakin and Mr A Tudor Edwards will open a discussion on the diagnosis and treatment of empyema. On November 12th a discussion on the medico-legal aspects of fractures will be introduced by Professor E Hey Groves and Dr James Neal. A clinical evening will be held on November 26th, and on December 10th Dr Wilfred Harris, Mr P J Verrall, and Dr James Brailsford will introduce a discussion on sacro-iliac pain. The Lettsomian Lectures, on dermatology in relation to other branches of medicine, will be delivered by Dr H W Barber on February 18th and 27th and March 6th, 1929. The annual oration will be given by Professor G Grey Turner, who has chosen cancer of the colon as his subject.

THE HALF YEARLY INDEXES

THE usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly, they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1. Those wishing to receive the indexes regularly as published should intimate this desire.

At the annual general meeting of the Royal Medical Psychological Association held last month at Wakefield a memorandum was received from the Parliamentary Committee of the Association on the Report of the Royal Commission on Lunacy and Mental Disorder. This memorandum was approved by the Council in July, and is now published as a supplement to the *Journal of Mental Science* by Messrs Adlard and Son, 21, Hart Street, W C 1, at the price of 1s.

APPLICATIONS for the Radcliffe Crocker Travelling Scholarship in Dermatology must be submitted to the committee of University College Hospital Medical School by September 30th. As announced in our advertisement pages this week, the scholarship is of the approximate value of £280, tenable for twelve months, to be spent at some place of study named by the School Committee, outside the United Kingdom. Further particulars can be obtained on application to the Dean of the School.

IMPORTED SURGICAL INSTRUMENTS

PROPOSED ORDER UNDER THE MERCHANDISE
MARKS ACT

The Standing Committee under the Merchandise Marks Acts, 1826, has recommended that an indication of origin should be borne at the time of sale or exposure for sale in the United Kingdom by imported goods of the following classes—surgical, medical, dental, and veterinary instruments and appliances, aseptic hospital and dental furniture, and dental supplies.

The report of the Committee, which is addressed to the President of the Board of Trade, states that the inquiry dealt with two references arising from applications for marking orders from the Surgical Instrument Manufacturers Association Incorporated and the Association of Dental Manufacturers and Traders of the United Kingdom—these were considered jointly at the request of the applicants. A group of between thirty and forty importers and dealers opposed the grant of a marking order. Eleven witnesses were heard at the inquiry on March 19th and 20th, a reference to which appeared in the *Journal* on March 31st (p. 581), and the members of the Committee conferred with representatives of the medical profession (Mr H. S. Souttar and Dr R. Wallace Henry, nominated at the Committee's request by the British Medical Association) and with officers of the Board of Customs.

The applicants stated that, in the absence of a mark of origin on imported goods of the descriptions affected, a purchaser would not know that he was buying imported material, and suggested that this confusion was increased by certain practices—such as the marking of goods in English, their description by English names in catalogues, importers representing themselves to be manufacturers, and sellers dealing in both British and imported goods. They asked that goods should bear an indication of origin, not only at the time of sale or exposure for sale, but also at the time of importation, and that wherever practicable a permanent mark should be required on imported goods.

The importers, on the other hand, stated that they were not concerned with dental instruments and the other dental goods included in the application and maintained that for the remaining goods a marking order was unnecessary. It was argued that the usual purchasers—surgeons, general practitioners, or hospital authorities—knew whether the goods were British or imported, and that a purchaser could easily distinguish between the two by the fact that British-made goods were generally marked, and by the difference in price. The importers contended, moreover, that nothing should be done to restrict the supply of essential instruments and maintained that the British manufacturers could not meet the whole of the trade demand. Objection was taken to an importation marking order on the ground that it would lead to serious delays at the Customs, while it was alleged that permanent marking would amount to a prohibition of importation since no medical practitioner would use instruments permanently marked with an indication of their foreign origin.

The Committee's Conclusions

The Committee concluded that in the absence of a mark of origin on the imported goods there is a reasonable possibility that purchasers may be misled as to their origin, especially having regard to certain catalogues which were brought to our notice at the inquiry. It is not prepared to recommend that any class of these goods should bear an indication of origin at the time of importation, mainly because of the administrative difficulty which would arise in connexion with the Customs and also because of the danger of injury to delicate instruments at examination. It also desired to avoid needless interference with the re-export trade. The Committee did not consider it necessary to require specifically that the goods should bear a mark of origin when exposed for sale by a wholesale dealer. A permanent mark is not regarded as essential to give the necessary information to the purchaser at the time of sale or exposure for sale; it is suggested that an indication on a label securely attached to the goods should be sufficient. It is pointed out that any permanent mark must be applied before importation, inasmuch as the marking of steel goods of these categories except at the time of manufacture would

not only involve injury to the goods, but would increase the difficulty of sterilization, and that the alternative of etching would not be practicable in the case of plated goods. Little evidence was placed before the members of the Committee in regard to parts of instruments, and it did not consider that the Order should apply to them.

Both parties agreed that large stocks of these goods were held, and that some of them were disposed of very slowly, but in view of the elastic nature of the methods of marking proposed, the Committee suggested that the proposed Order in Council should come into force three months after it was made. An annex to the report, giving the full recommendations regarding the classes of goods covered by the proposed Order in Council and the methods of marking to be employed, reads as follows:

Recommendations as to Marking

1. The following classes and descriptions of imported goods shall bear an indication of origin at the time of sale or exposure for sale in the United Kingdom—namely:

(a) Surgical, medical, dental, and veterinary instruments made wholly or mainly of metal.

(b) Surgical, medical, dental and veterinary appliances of all descriptions not including artificial eyes.

(c) Aseptic hospital furniture made wholly or mainly of metal including operation and examination tables and chairs, instrument and dressing tables, ward lockers, instrument and dressing cabinets, sterilizers for instrument dressings and bowls.

(d) The following classes of dentists' supplies: Artificial teeth, absorbent wool rolls and pellets, abrasive points, strips and discs, dental rubber, rubber dam, gutta percha, temporary stopping, dental wax of all descriptions, impression compound of all descriptions, dental cements and amalgams, and foil, crowns, discs, solder, cylinders, plate and wire of gold, platinum, and other precious metal.

(e) Dental furniture including dental chairs as well as bases, bodies and headrests therefor, instrument tables, lockers, dental cabinets and dental cuspidors.

2. The indication of origin shall at the option of the person by whom it is applied be given as follows:

(a) die-marked, etched, or otherwise impressed on the article itself; or

(b) printed or stamped on a label securely affixed or attached to the article; or

(c) in cases in which the article is habitually sold or exposed for sale in a case or other container or fixed on a card, printed, stamped or impressed on the case, container, or card.

CONTROL OF DANGEROUS DRUGS

HOME OFFICE ANNOUNCEMENTS

IMPORTANT changes in the regulations governing the traffic in dangerous drugs are announced in two official communiques issued by the Home Office on August 17th. The first relates to the extension of the control exercised under the Dangerous Drugs Act, 1920, to cover certain morphine derivatives and other drugs, and the second to the coming into operation of the Dangerous Drugs Act 1925. This new measure gives effect to the International Opium Convention of 1925, which comes into force in September, and which was discussed in the *Journal* of July 21st (p. 117). The Home Office communiques are as follows:

Extension of Control

The Home Secretary wishes to draw attention to the fact that by Order in Council, made under Section 8 (2) of the Dangerous Drugs Act, 1920, Part III of that Act, which provides for the control of morphine, heroin and cocaine, has been applied to the following drugs: benzoyl-morphine, dihydro-oxycodone, dihydro-codeinone, and their respective salts, and to any preparation, admixture, and extract containing them. Benzoyl-morphine is an ester of morphine which, because it is not subject to the International Opium Convention and because morphine can be easily recovered from it, has been manufactured recently in large quantities on the Continent for export to the Far East. The League of Nations has recommended that its manufacture, sale, etc. should be controlled in the same way as morphine. Dihydro-oxycodone and dihydro-codeinone are produced as pharmaceutical products usually in the form of salts by certain German firms under the trade names of 'Ludodal' ('Lukodal') and 'Dicedido' respectively. The League has reported that these drugs

¹ Cmd. 3148. London: H.M. Stationery Office or through any book-seller. 1934. 2d. net.

possess similar narcotic properties to those of morphine, and recommended the application of the same system of control. None of these drugs is manufactured, so far as is known, in Great Britain.

International Opium Convention, 1925

The Home Secretary gives notice that the Dangerous Drugs Act, 1925, which was passed to give effect to the International Opium Convention of 1925, will come into operation on September 25th next, the date on which the Convention comes into force. The chief alterations made by the new Act will be the extension of control to Indian hemp and the resin obtained from it (hashish) and any extract or tincture of Indian hemp, and to preparations containing less than 1/10 per cent of diacetyl-morphine (heroin), which up to now have been exempted. After September 25th a licence will be required for importing or exporting any of these drugs. The Dangerous Drugs Act, 1925, will modify the definition of medicinal opium for the purposes of the Dangerous Drugs Acts. It will mean in future raw opium which has undergone the processes necessary to adapt it for medicinal use in accordance with the requirements of the *British Pharmacopoeia*, whether it is in the form of powder or is in any other form, and whether it is or is not mixed with neutral substances.

EDUCATIONAL ADVANCE AND THE MIXED SCHOOL

If it be the duty of the family physician to advise as to the upbringing of children, it is clearly necessary for him to have a real acquaintance with the educational system of the country and a knowledge of the main problems with which teachers and education administrators are concerned. This becomes the more urgent in so far as the practitioner of medicine realizes that his business must necessarily lie not merely with physical conditions, but with mental and other aspects of the human individual, and not merely with the cure, or even avoidance, of ill health, but with the more complete development of what bodily or mental powers the whole personality possesses. Health and education are thus seen to be but two aspects of the same subject. Recent proposals for the radical modification of educational organization in England and Wales should, therefore, be of great interest to the medical profession as to others.

In the *Journal* of January 15th, 1927, we gave considerable attention to the report, then just published, of the Consultative Committee of the Board of Education on the "Education of the Adolescent," both in a special article (p. 114) and a leading article (p. 107). In spite of the fact that the main proposals of that report were welcomed almost unanimously by education authorities, administrators, and teachers alike, the President of the Board of Education immediately issued a pronouncement that he did not propose to adopt the most important and urgent of these proposals, and he has since done but little to encourage the adoption of any of them. The Board of Education has now, however, issued a pamphlet entitled *The New Prospect in Education*,¹ in the hope that it may assist towards the solution of problems of organization in connexion with the provision of proper educational facilities for older children on the lines suggested in the Consultative Committee's report. Along with this may well be considered an excellent presentation of the case for the co-education of boys and girls just published by the University of London Press under the title of *The Mixed School*,² by Mr. B. A. Howard. The problems have obviously a close connexion.

The provision considered in the Board of Education pamphlet is that which would be needed constitutionally upon the adoption of the Consultative Committee's recom-

mendation that there should be secured for all pupils (not merely a selected number as now) a break at the age of 11 years, or just over, and a fresh start at that age on a definitely new stage of education in schools of varied types. Although recognizing that this has become the "generally accepted basis of all reorganization proposals" the pamphlet contains plenty of evidence of the continuance of what was described in our previous article as "the present discouraging temper and restrictive policy of the Board of Education." It emphasizes to an almost depressing degree what has come to be called "the inevitability of gradualness," in spite of the fact that local education authorities are as an organized body almost clamouring for central action to be taken in order to avoid the disadvantages inherent in action taken by individual areas. It stresses over and over again, and in our opinion unduly, the recognized difficulties which have to be overcome and which are very real in some areas. It almost ignores, or even actually obstructs, the two prerequisites of the proposed post-primary schools if they are to be successful—a four years' course to the age of 15 years, and smaller classes. The need for both these was stated by the Consultative Committee, which urged that the former should be enacted so as to take effect in the year 1932. The Board postpones the raising of the school age indefinitely, and states as the "reasonable provision" for a senior school of 400-440 pupils, 6 classes of 40 each and 2 classes of more than 40, with none below that number! However, it seems likely, if the present attitude of the Board of Education be maintained, that the large and progressive authorities, whether county or urban, will be in advance of the Board, and that, if the Board will allow them they will have established in their areas within the next eight years a system by which all children (except a relatively small number who may be exempted in their last year) will be educated in a junior school till the age of 11 (or in an infant school from 5 to 8 years and a junior school from 8 to 11) and in a senior school (of one type or another) till 15 years of age, and that an increasing number of such children will voluntarily stay on in school for one, two, or three years more. Not only will these senior schools be of varied types as a whole (the present "secondary," "central" and "junior technical" schools are such types), but within themselves they will offer in their later years alternative courses to individual pupils.

It is evident that in such a scheme all the children up to the age of 11 years, or a little over this age, would be educated in mixed school. The interesting question arises as to whether, or how far, it is desirable that boys and girls beyond that age should be placed in separate schools, or whether the co-education of the sexes should continue. In a circular issued more than three years ago the Board of Education stated that it was strongly in favour of separate departments for senior boys and senior girls. One would have thought that it might now be less dogmatic, but it still states that "there is no reason to depart from this view, but in less populous areas it may be necessary to establish mixed schools in order to assemble enough children to form a separate senior school of reasonable size." The Board thus regards the mixed school merely as a disagreeable economic necessity. It is not quite evident why it should do so. A large number of expert and practical educationists and a considerable number of education authorities do not agree with this view. In America and in all the Scandinavian countries co-education is throughout the normal method. In this country the first-class boarding schools of the Society of Friends have been of this character for a hundred and twenty years and more recent two outstanding privately owned schools coming within the rank of what are called public schools, have been deliberately established on this principle. Bedales School, near Petersfield, founded in 1893 and St. George's School at Harpenden, founded in 1907. Speaking only a few weeks ago at the coming of age celebration at the latter school the Duchess of Atholl Parliamentary Secretary to the Board of Education more open-minded than her department, said that "of all experiments none was more interesting or fruitful with greater possibilities for the welfare of the country than the experiment of co-education, it seemed unquestionable

¹ *The New Prospect in Education*. Board of Education Educational Pamphlets, No. 60. London: H.M. Stationery Office, 1928. Price 6d net.
² *The Mixed School*. By B. A. Howard, M.A., Head Master, Adley and Stanhope Schools, London. University of London Press, Ltd., 1928. (Post 6ro pp. 238. 6s. net.)

that if boys and girls had grown up together, worked together, and played together, they should be able to enter on life with a knowledge of the mentality and habits of their sexes which should be a very valuable guide to them."

Some of the foremost local authorities in the realm of higher education have deliberately adopted the policy of encouraging the provision of mixed secondary day schools. The county council of Middlesex is an example. Of the secondary schools for which that council is responsible twelve are for boys only, nine for girls only, and seventeen are mixed. It is interesting, possibly instructive, to note that in these schools, judged by examination results, the boys in the mixed schools do better than those in the boys' schools, and the girls in the mixed schools better than those in the girls' schools. The arguments, of course, are not all on one side, nor is any class of school without its imperfections and disadvantages.

We could not desire a more reasonable statement of the problem or of the case for co-education, than Mr Howard gives in his book on *The Mixed School*. It is clear and comprehensive in presentation and argument, interesting in style, moderate and fair in tone and has on almost every page an acceptable touch of wit and the right sort of humour. Mr Howard deals with the question from the point of view of history, of morals, of society, of pedagogy. He then considers certain special difficulties to which co-education may give rise, and some of the specific objections which are raised against it. He rightly emphasizes the fact that many of the difficulties and objections or all kinds are really common to schools of all types and not peculiar to mixed schools, and that co-education does not necessarily mean identical education. The physical differences between the sexes necessitate that for games and physical exercises there must be separation of boys and girls in the gym, and a mixed school should offer to individual pupils an even greater variety of choice in scholastic and manual work than is available in an ordinary school. It is claimed that the mixed school is not only theoretically the more desirable, but that in practice, given proper staffing and management, its difficulties disappear and its advantages become more and more evident.

Ireland.

Public Health Congress in Dublin

THE annual congress of the Royal Institute of Public Health which opened in the Mansion House, Dublin on August 15th was attended by approximately three hundred delegates, representative of Great Britain, Ireland, the United States, America, France, Switzerland, India, the British Dominions, and other countries. The delegates were cordially welcomed on behalf of the city of Dublin by Mr Commissioner Murphy, the Reverend Dr Westropp Roberts, Vice-Provost of Trinity College, Dr Denis J. Coffey, President of University College, Dr W. A. Winter, President of the Royal College of Physicians of Ireland, Mr T. F. Gordon, President of the Royal College of Surgeons in Ireland, and Dr Edward Magee, President of the Apothecaries' Hall, Dublin. The presidential address was delivered by General R. Mulcahy, Minister for Local Government and Public Health in the Free State. Sir Thomas Oliver, M.D., Vice-Chancellor of the University of Durham and chairman of the council of the Royal Institute of Public Health, said he had great pleasure in asking General Mulcahy to accept the honorary fellowship of the Institute in recognition of his eminent services to public health. The King and the Prince of Wales sent messages wishing success to the congress. The delegates were entertained at a garden party given by the Governor-General, Mr James McNeill, and Mrs McNeill. On Saturday, August 18th, they took part in excursions to Killarney, the international motor race at Belfast, the Shannon engineering works and a visit to the Dublin Corporation Waterworks at Roundwood Co. Wicklow. On the last-named excursion President Cosgrave accompanied the delegates, who were the guests of Dr Myles Keogh, T.D.

Medical Inspection of School Children

A report on the medical inspection of schools, issued by the Free State Ministry of Local Government and Public Health, states that the first local authority to establish a school medical service was the county borough of Cork, in 1924. As a preliminary the school medical officer made a general survey of the physical condition of the children attending the twenty-seven national and other elementary schools coming within the scope of the scheme, in order to obtain a basis of comparison and to gain an insight into the purposes to which further progress might be most usefully directed. The results of this examination were as follows: children examined, 11,286, children tested with Snellen's types, 8,166, suffering from defective teeth, 69.9 per cent, defective eyes, 22.5 per cent, defective nose and throat, 5.8 per cent, minor ailments, 9.4 per cent, malnutrition, 8.0 per cent, in a state of uncleanness, 11.8 per cent. During 1926 the following received treatment: (1) at Eye, Ear, and Throat Hospital and by private practitioners—(a) operation treatment, 103, (b) refraction, 511, (c) glasses prescribed, 503, (2) at Dental Hospital and by own dentist, 1,054, (3) at school clinic—minor ailments, 359, (4) provision of surgical appliances, 3. The only other local authority to adopt a scheme in 1924 was the Clonmel Corporation. In 1926 1,335 children were inspected, 223 of whom received dental treatment. A scheme is now operating in Dublin, and it is hoped to inaugurate schemes in the counties of Cork, Carlow, Kildare, and Offaly this year.

Censorship Proposals in the Free State

The Censorship of Publications Bill, which was read for the first time in the Dail before its adjournment, is in many of its aspects of considerable interest to the medical profession. The bill provides that, in addition to books, periodical publications which are found to be usually or frequently indecent or obscene, or have generally tended to inculcate principles contrary to public morality, will also be banned on advice from the Censorship Board. The importation, sale, or distribution, except under special permit of any banned publication will be punishable by a fine not exceeding £50, or by imprisonment up to six months. A register of prohibited publications will be kept in Dublin and will be open for inspection free of charge. Customs authorities will have power to stop the import of banned publications and the postal authorities will also have power to prevent the post office being used for their distribution. It is proposed to extend the Indecent Advertisements Act (1889) to apply to advertisements relating to sexual diseases or questions, or to drugs, medicines, appliances, treatments, or methods of procuring abortion or miscarriage or of preventing conception. Offences under this part of the Act are to be met by fines not exceeding £25 or imprisonment not exceeding six months. The sale or distribution of indecent pictures is also banned. The police will have power on warrant to search places suspected of keeping such pictures for sale or distribution. Regulations will be made prescribing the manner in which complaints will be made to the Minister and the procedure of the Censorship Board, the officers and servants of which will be appointed at such remuneration as the Minister of Finance may determine. The bill will come up for second reading in the Dail in October.

England and Wales.

University of Liverpool Gynaecological and Obstetrical Department

PROFESSOR BLAIR BELL has republished in monograph form a series of papers contributed to the *Journal of Obstetrics and Gynaecology of the British Empire* on the material and methods of the Gynaecological and Obstetrical Department in the University of Liverpool. In order to set forth the minimum requirement of a clinic of this kind and assist those who may have to organize a new clinic. The ground floor plan of his department, with its lecture

thiatric, museum, laboratories, research and private rooms forming a compact and self-contained unit, will be the only of, and an ideal to be hopefully pursued by, many who have to train future medical practitioners without the "minimum requirements of a complete obstetrical and gynaecological clinic," as therein set out. The classification of the museum specimens and the arrangement of subjects in the lecture course are scientific and sound, and will be of particular interest to teachers. Systematic lectures are clearly made a feature in the Liverpool school, seventy being given for each course, and of these the subject-matter of the first fifty-nine is given, the statement being made that the remainder are devoted to gynaecological operations and procedures as time allows. The allocation of time among the various subjects will not appeal to all, for there appears to be an undue proportion of lectures devoted to gynaecology, considering its lesser importance in practice as compared with obstetrics. While no lecture is specifically devoted to ante-natal supervision or the preventive aspect, this side is doubtless considered throughout the sixteen lectures devoted to the disorders of conception, parturition and the puerperium, the four lectures on obstetric operations, and the lecture on foetal injuries. All the lectures are illustrated by lantern slides, an average of about twenty slides being used for each. Those parts of the monograph in which the arrangement of the out-patient and in-patient departments and operating theatres in the Liverpool Royal Infirmary is described and illustrated will be of interest to more than teachers, and the whole monograph is one on which Professor Blair Bell may be congratulated. He has performed a useful service which might well find imitators among the directors of other departments and in other universities and schools.

Preston Hall Tuberculosis Settlement

An interesting account of the working of an occupational therapy centre for the treatment of consumptives is given in a report on the British Legion Village, Preston Hall, Kent, which has been prepared by the medical director, Dr J B McDougall. This settlement has been devoted to the treatment of ex-service men for over three years, the establishment now consists of the Hall itself, used as the sanatorium, with beds for 66 patients, hut shelters accommodating 48 patients, two hostels providing for 13 and 38 patients respectively, and the "village," with its miniature streets of cottages, its village hall, and various workshops. At the end of March the permanent population of the settlement was 654, there were 131 patients in residence in the sanatorium, and 122 male settlers (ex-patients) in the village, of whom over 100 were married men living with their wives and children. These men, together with a number of the patients, find employment in the industries of the settlement, which comprise the appliances department (producing all kinds of portable buildings, from rabbit hutches to bungalows), the building and joinery department, the manufacture of fibre and leather goods, printing, farm and gardens, stores department, administrative department. Preston Hall is modelled upon the larger and better known Papworth Colony, whose medical director, Dr P C Vairnei-Jones, undertook the reconstruction of the settlement in 1925, and was responsible for its administration until 1927, when Dr McDougall assumed charge. It will be recalled that an account of the Papworth institution was published on June 30th (p 1115). Dr McDougall, in his report, deals in equal detail with the medical and economic aspects of the work, and gives an interesting summary of the financial position of the scheme. The three fundamental principles are described as (1) the treatment and education of the patient suffering from pulmonary tuberculosis, (2) occupational therapy, and (3) adequate after-care for those who have passed successfully through the earlier stages by the provision of permanent employment and residence in the village settlement. Patients at Preston Hall who make satisfactory progress and are judged capable of exercising for four and a half hours each day are drafted into the industries, the reasons for this step being carefully explained, and emphasis being laid upon the fact that the work is equally important from the medical and the economic point of view. Apart from

the possibility it offers of restoring to the patient his economic independence, the exercises afford a means of testing his resistance, medically and economically, to the disease from which he is suffering. The conditions to be satisfied before a patient can become a settler and a permanent member of the community constitute a severe test of his capacity. He must be capable of working for at least thirty-eight hours each week, and must be efficient in the work in which he has been trained while a patient, the industries, further, should be in a position to maintain him and to provide a reasonable wage for his work. In effect, therefore, each settler must be, within the limitations of the scheme, economically sound. In the three years covered by the report, out of 620 patients admitted to the sanatorium suffering from tuberculosis of the lung at all stages of the disease, 91, or 14.2 per cent, have been admitted to the settlement and given permanent employment. It is stated that any lowering of the standard of admission would necessitate the payment of a substantial subsidy for maintenance. A feature of some interest is the surprisingly high number rejected as settlers owing to unsuitability on temperamental grounds. Of 207 patients sent to the industries with a view to graduation as settlers in 1927-28, 68 were found to be inefficient and 66 were regarded as likely to become efficient but were temperamentally unsuitable, or were forced to leave for domestic reasons, or were discharged on disciplinary grounds. Many have been unable to adapt themselves to the requirements of the new environment. The remainder of the 207 patients includes those accepted as settlers, those awaiting admission, and those whose status is not yet decided. Dr McDougall holds that, on a national scale, it would be impossible to make settlement treatment available for more than a percentage of all cases, and he believes that, without a subsidy, it would be difficult to secure generally the progressive expansion in the industries which has been possible at Preston Hall.

We regret to add that since the issue of this report the Preston Hall workshops have suffered considerable damage from an outbreak of fire which occurred on August 14th. According to newspaper accounts over 50 per cent of the settlers will be thrown out of employment. It is to be hoped that it will be possible to reconstruct the damaged workshops and resume operations fully at an early date.

The Hayling Island Mosquito Control Institute

The first annual report of the British Mosquito Control Institute, Hayling Island, provides evidence of the steady growth of a campaign which is likely to be of increasing value in the prevention of malaria. A year ago (August 20th, 1927, p 325) we mentioned briefly how this organization came into being, and the fact that many distinguished parasitologists, including Dr Andrew Balfour, Professor Balfour-Browne, Sir Ronald Ross, Sir William Simpson, and Dr C M Wenyon, are members of the council indicates the importance of the work, of which Mr J I Marshall has acted since the outset as honorary director in a special building erected at his own expense. In addition to being the only organization of this kind which is devoted entirely to mosquito control research, the Institute embodies a mosquito control scheme in actual and continuous operation. Advice relating to prophylaxis and the treatment of infested areas is supplied by correspondence and by visits of experts from the Institute, which frequently result in the inception of active campaigns, including the necessary treatment of mosquito-breeding neighbourhoods. Two-day instructional courses in laboratory and field work are given at the Institute, commencing on the first Tuesday in each month. These courses will be of special interest to sanitary officers, to persons contemplating foreign travel or residence abroad and to those who wish to obtain general knowledge about the subject of mosquito control. Beyond the lectures and laboratory work, practical field work is arranged, including the surveying of an area containing breeding places, the collecting of larvae and mosquitos, and the various methods of applying oil and larvicide to infected water. An illustrated booklet describing these educational courses can be obtained gratis from the secretary of the Institute. Facilities for research work are available, and a reference library is being built.

up In the director's report it is mentioned that lectures on mosquito control have been given in different towns during the year under review, and it will be recalled that the Institute was responsible for an exhibit at the convocation of the Royal Society in May (*Journal*, May 26th, p. 912)

Correspondence.

ESTIMATION OF PUERPERAL MORBIDITY

SIR.—From the very interesting note in last week's *British Medical Journal* (p. 321) the impression might be got that we do not use the "Rotunda" method of estimation of morbidity at the Rotunda Hospital. I revived this method of estimation (which was started by Dr Tweedy and which we always call the "Rotunda" method) when I was appointed master in November, 1926. In addition, I use the British Medical Association standard. The "Rotunda" method is as follows:

A patient is considered morbid if the temperature and pulse concurrently are above 99° F and 90 per minute respectively, on three consecutive occasions from the second day to the day of departure from the hospital.

I have revived this method in order to determine whether the health of the institution can be better estimated thus. A patient is not morbid, according to the British Medical Association standard, if fever occurs only after the eighth day. It is interesting to note that last year the rate by each standard was the same.

It is very important, when making up annual statistics of morbidity, that certain patients should only be considered, and that an estimation should be obtained of the number of women delivered, not admitted.—I am, etc.,

BETHEL SOLOMONS,
Master Rotunda Hospital.

Dublin Aug 18th.

THE GUILLotine AND ETHYL CHLORIDE

SIR.—We should be thankful to Mr Stuart Carruthers (August 11th, p. 273) for his criticism of the theatre administration outlined in Mr Sandiford and Dr Clayton's paper (July 28th, p. 149), and for telling us of the high state of perfection to which he has brought his own. Yet even Mr Carruthers appears to range himself on their side as "the surgeon in a hurry" when he says that he can deal with twenty cases in an hour.

There are many who think that this hurry is wrong. It was Sir William Milligan who first suggested to me that from the moment the patient is put on to the table to that at which he is lifted off again the time should never be less than ten minutes, but in clinics of teaching schools where assistants, both of the medical and nursing profession are always inexperienced learners, it should, in my opinion, be not less than a quarter of an hour.

In this operation tragedies of an irrevocable nature may arise with lightning rapidity. These are best prevented by everything being done decently and in order, without any haste, and with the full attention of all concerned directed upon doing the operation rather than upon getting it over. When they arise immediate action of an appropriate nature is needed, and to do the right thing at the right moment is the harder the higher the pitch at which all are working.

Only to-day has arrived the text of the Registrar-General's statistical review for 1926. In it we learn (p. 109) that the number of deaths has again jumped up by a further 25 per cent to the appalling number of 556 and of these 32 were during operations upon tonsils and/or adenoids (p. 112). Great as must be our sympathy with those of our colleagues to whom these tragedies have occurred yet we cannot deny that these are thirty-two unnecessary deaths. In major abdominal operations a few minutes saved may be a factor in the recovery of the patient and in persons desperately ill every second may be of value, but in the great majority of operations surgery in a hurry is wrong and it is reasonable to suppose that the practice of operating with the eye on the clock, which has been so much to the fore in the last

decade, may be associated with the constant rise in the number of deaths under anaesthesia in the same period. Team work may be an essential part of modern surgery, but if it be designed to get through the work quickly rather than to do it with efficiency and greater safety to the patient, then we are better without it.

I regret the more those parts of Mr Sandiford and Dr Clayton's paper that have been criticized, because in the rest of their paper they have given a good description of the reversed guillotine method of enucleation of the tonsil—though, with Mr Carruthers, I do not like avulsion—and any such description will do good in counteracting the influence of those who say that every tonsil must be dissected out and who repeat the incorrect statement that no tonsil ever was or ever can be enucleated with the guillotine. For many years this school has appeared more often in print than their numbers warrant, and anything that will counterbalance their influence is of value. It is a pity, then, when the effect of such an article is impaired by matters to which objections may be raised—I am, etc.,

Guy's Hospital S.E.1 Aug 13th

T. B. LAYTON

THE CURSE OF NOISE

SIR.—Some twelve or thirteen years ago I published a small book to draw attention to the modern plague of noise and to appeal for its reduction. So much has the plague increased since then that I might as well have spared myself the trouble. All the same, noise makers are not having things all their own way, and the ever-growing irritation of our long suffering community is at last working itself up to the determination that all harassing and unnecessary noise has got to stop. The time is past for invective, no matter how eloquent. What we want is action.

Government departments approached for help murmur sympathy, but confess impotence, they find themselves without power to act. Only Parliament is able to grant that power, for which reason we, as a profession, should certainly give our warmest support to any bill introduced into Parliament to this end.

Difficulties will arise, no doubt, but, as difficulties so often do, they will vanish when confronted with the weapon of common sense. Someone is sure to ask, for example, "How can you give a legal definition of a 'noise'?" The answer to that apparent poser is simple. If a sanitary inspector can distinguish between an inoffensive odour and a smell which is equally a "nuisance," surely it will be quite as easy for him to decide when a sound becomes a "noise," and equally a "nuisance," that is to say, something not only objectionable in itself but also injurious to health.

To deal with what we may call stationary noises then, would seem to be simple enough. But what about the ever-increasing rush and roar of motor traffic, from which we are all of us sufferers and in which we are most of us also transgressors? On the former occasion I ventured to urge the total abolition of the motor horn, a proposal that may seem to be rather too radical, since it would mean that we should have to rely wholly upon the skill and caution of drivers. Yet even here opinion seems to be changing, for quite recently there has been advocated the constitution of "zones of silence" in the domestic parts of our cities wherein no motor horn shall sound—obviously the thin end of a wedge that will lead sooner or later to the silencing of all horns and hooters. In practice, as a matter of fact, it is quite safe to dispense with them, since without his warning hooter a driver is forced to be much more cautious.

The most objectionable type of motor vehicle is, of course, the ponderous lorry that comes thundering along our empty streets at dead of night and not only wakes us up in a panic but even makes the floors and walls of our dwelling-houses quiver and tremble. The passage of such bone-shakers through our dormitory-streets, by night at least should be absolutely prohibited.

Efforts to abolish or minimize public noise as a little consideration will show, will produce, however, some far-reaching effects of commercial importance, so that it is

from the business world that opposition to reform is likely to proceed. On the other hand, what is equally true is that as the solution of the noise problem is in the long run an engineering duty, engineers, faced by the necessity of devising comparatively noiseless machinery, will certainly succeed in doing so. And in the speeding up of this desirable transformation the pressure of an Act of Parliament will undoubtedly exercise a powerful and lasting influence.

There is no need at this time of day to labour the point that the matter is one of the public health, whether the noise be produced in factories, workshops, or streets. That being so, it is fitting and proper that the British Medical Association should charge itself with the drafting and passage of such a bill with as little delay as possible—I am, etc.,

London W 1 Aug 19th.

DAN MCKENZIE

SIR,—May I be allowed to say that Dr Harvey Hilliard's suggestion (August 11th, p. 276) that a bill to suppress unnecessary noise should be promoted in Parliament seems to me a sound one. A similar suggestion is made in a letter in this morning's *Times* by the late Warden of New College. Probably such a bill would find much support in the House of Commons, but its opponents would doubtless detect its weak points and at once point out the difficulty of defining harmful noise and that of the measurement of the quality and quantity of sounds. It may be assumed, however, that all angry passions are harmful to their host always and sometimes to their objects, and the violent disturbance of one's attempt, or slumber, rouse furious rages in many of us. Such sufferings as those described by Mr Arthur Baumann and others in the same paper are unquestionably harmful. I have myself lately escaped from somewhat similar afflictions.

Until a year ago I lived in a street which had become a by-pass for Oxford Street and a direct route from Bayswater to the East and North-East, and vice versa. The heavy lorries and motor cars shoal and shocked us day and night, so much so that a year or so since a neighbour's house front had to be partly rebuilt. At night hurrying cars would utter four or five nerve-wracking hoots at the cross-roads nearly under my windows, and repeat them at each quickly succeeding cross-road till the sounds died away somewhere near the Middlesex Hospital, by which time other cars had taken up the chorus and drowned more distant sounds. But the *bête-noire* to everyone in the house was a certain lorry which passed regularly about midnight, laden with milk cans and with many loose and resonant parts. Its speed was inestimable and it shook the whole house. I can only compare the din to that of a fast goods train on a badly laid track when checked by the engine brakes. It is true that Sunday brought a cessation of the lorry thunder, but it brought an increase of motor hooting at night from cars returning late from devastating excursions to the countryside and hurrying to their homes on the other side of London. Happily I escaped from this inferno of din last summer, and now rejoice in a flat, which *up to this time* is not noisy in the day and is quiet at night. The unfortunate speculator who bought my lease has not yet been able to find a tenant. A deaf family, whom it would suit admirably, does not seem to have come that way.

There are two measures which seem to me practical and possible. These are the entire suppression of all solid tyres and the prohibition of the use of motor horns at night. The forty-mile-an-hour driver appears to think that if he hoots loudly and often enough he need not slow down at cross-roads. If he were not allowed to hoot, he would have to go slower and be more careful. As for the motor cyclist, the process by which he chainmates himself and his friends should be speeded up. The present rate of mortality is too small, for our comfort. Let me end this too long letter on a note of thankfulness. The war did away with the terrible cab whistle and nearly all the hoarse bawling of the latest edition hawker—I am, etc.,

London S W Aug 18th

E. MUIRHEAD LITTLE

TROPICAL AUSTRALIA

SIR,—With reference to the correspondence in your columns on tropical Australia, I know nothing of "the percentage of white Queenslanders who carry out manual labour in the open, under the trying conditions obtaining in the coastal region, who are Italians or of Italian origin," but nearly twenty-five years ago I was in charge of a country hospital at Burketown, situated in the low lying coastal area of the Gulf of Carpentaria, and I do know that practically the whole of the white Queenslanders were of British origin, and that the menfolk who laboured in the open air were of a type that I have not seen surpassed anywhere.

Two facts were impressed on my mind: (1) the necessity for open-air exercise (work) in a hot climate, (2) the unfortunate housing conditions under which the women had to live, most of the so-called houses being constructed of corrugated iron, very hot in summer, and bitterly cold in winter (natural ice in winter I saw quite often). Malaria was still evident, but not the widespread disease I had anticipated. It would be on account of the extensive swamps. I have not the slightest doubt, from what I have seen, that British stock can work and thrive in our northern country, provided they have suitable housing and ample open-air exercise (work), and also provided they take alcohol only in moderation, or preferably not at all—I am, etc.,

ERNEST CULIN, M.B., Ch.M.

UNSUCCESSFUL FORCEPS CASES

SIR,—I have read with great interest the papers by Dr Douglas Miller, Dr James Hendry, and Dr Fletcher Shaw on the above subject, published in the *British Medical Journal* of August 4th. They seem to be in a bad way in the North, their description of the cases put before them out-Herods Herod, and calls for deep thought as to the teaching in their universities.

From a practitioner's point of view it cannot be too strongly put, and ought to be an accepted axiom, that no artificial delivery should be attempted until there is full dilatation of the os. If Nature fails, Champetier de Ribes' bags or some other recognized method should be used to accomplish that end before anything else is done.

The position of the head should be clearly ascertained and the passing of the head, under an anaesthetic, is the simplest and least manipulative in the long run. When an occipito-posterior presentation is diagnosed it has to be rectified. The case has already been considerably delayed. If the head is rotated bimanually there is always the chance of its returning, for Nature placed it so and the cause not being rectified must make it liable to recur.

In a patient with a reasonably sized bim, surely with the hand already there the easiest and safest method would be to bring down a leg and turn. I am very much surprised that Drs Miller, Hendry, and Shaw in their addresses have not mentioned turning, it is certainly scientific and puts Nature at its best. The bones of the head in descent will be compressed from below, causing folding over of the edges of the parietal bones, giving considerable room, and avoiding the tedious moulding spoken of, much to the benefit of the child and mother. With the head in the pelvis and the occipito-posterior position persisting the head must be returned above the brim to rotate, and, having returned it, I should advocate bringing down a leg every time—a very simple procedure, with little or no handling, and needing no force, only steady traction.

Perhaps I am old fashioned, but I have a great horror of the callous way in which a woman is left hour after hour fighting to produce the moulding of the head, which one would think must bruise and compress the child's brain out of the normal shape, let alone mauling the woman's soft parts oedematous and sodden, and facilitating the entry of germs. The mere fact that moulding is necessary shows an abnormal state of things. Even when the forceps are required for the after-coming head it is quite simple, and the head is again in the right position to

produce most folding over of the parietal bones. I think Nature points the way. A breech birth is a normal birth, why try to avoid it?—I am, etc.,

A Z C CRESSY

DUT AND PULPERIAL SIPSIS

Sir,—In the discussion of the problems connected with maternal mortality I have failed to notice what appears to me to be an extremely important possible cause of puerperal infection.

If underneath the room in the house or nursing home in which a pregnant woman was awaiting confinement there ran a leaking sewer, she, her nurse, and her accoucheur would all insist on her going elsewhere in view of the risk of infection.

In a high percentage of human beings under modern methods of dietary the lower alimentary canal is somewhat in the nature of a sewer. Examination of the faeces demonstrates that in a very considerable number of cases septic organisms are present in large numbers. What happens, therefore, is that delivery takes place very often in close proximity to a possible source of septic infection.

The mere giving of an enema or a series of purgative medicines has been shown to be of very little efficacy in reducing the septic condition of the alimentary canal, while antiseptic drugs have proved to be equally valueless. The wiser method of diminishing these organisms is by a sufficiently long course of dieting designed so that no food should be provided suitable for the organisms that we wish to get rid of.

Roughly speaking, the alimentary canal of a horse or a cow out on grass is free from dangerous micro-organisms, although the alimentary canal is considerably elongated in these animals. In carnivorous animals Nature gets over the difficulty of the dietary by extensively shortening the intestines. In the human animal, however, the intestine is similar in length and character to that of the frugivorous anthropoids. The lower intestine has a tendency, therefore, to become an infected sewer when constipation and flesh eating are associated.

The surgical method is to remove this piece of intestine. The more natural method is to use a dietary by which infection is avoided. In countries where coarse cereal foods and plenty of oil and salads are used the addition of a small amount of meat is unimportant, but in countries like England where most of the foods are ultra-refined, and where a high proportion of stall fed fattened beasts' meat is eaten, constipation is very prevalent, and a septic condition of the lower intestine follows.

Dietary therefore, in childbirth is a matter of supreme importance in the prevention of puerperal sepsis. Meat should be eliminated from it, salads and vegetables should be used largely purged and similar cereal dishes should replace the finer preparations of oat and wheat, oil and butter should find a considerable place while the proteins should be obtained from cheese, milk, and nut foods during the whole period a mother is carrying her baby.—I am, etc.,

London W 2, Aug 13th

JOSIAH OLDFIELD

INSECT BITES AND RHEUMATISM

Sir—I am anxious to secure the co-operation of medical practitioners throughout the country in obtaining information regarding children who are badly bitten by insects at this time of the year.

I believe such children, especially those whose bites develop into sores, are the very ones who are predisposed to acute rheumatism and chorea. These children do not drink milk, either on account of poverty, or dislike, and unfortunately at the same time aggravate this lack of lime food by having a perverse appetite for acids like vinegar or lemon. The latter part of the summer is the time when the children are badly bitten by fleas, sand fleas, harvest bugs, and midges, and it is within the next month the cases of acute rheumatism and carditis tend to show themselves.

It is interesting to note that the areas in which the human flea flourishes are coincident with those of acute

rheumatism, the tropics being free from both. One cannot help being struck by the fact of the periodicity in the viciousness of most of these insects, including fleas. Personally I feel convinced that the course of acute rheumatism is more that of a disease due to a protozoon than one due to coen, and I have made the suggestion that the Aschoff bodies are probably the encysted forms of the protozoon responsible for acute rheumatism, though it is only fair to say that Professors Nuttall and Kettle are not prepared to accept my hypothesis.

I shall be very grateful to readers who will be so kind as to collect information for me on these lines and write to me on the subject.—I am, etc.,

SEA SICKNESS

Sir,—There has been considerable correspondence lately in the *Journal* on the subject of sea-sickness (June 23rd, p 1089, etc.), and I am surprised that no one has mentioned the respiratory disturbance associated with this malady, I believe it is the most important factor in precipitating an attack.

Sea-sickness is largely a question of temperament, and those who are most prone to it belong to the nervous, or neurobilious type of constitution. It is people of this class who, under appropriate emotional excitement, give a "sigh of relief," a "gasp of astonishment," a "cry of joy," a "scream of terror," all of which are accompanied by abnormal respiration. Likewise, these people feel nausea from excitement, apprehension, suspense, or at horrifying sights, also, they hold the breath whilst running, or carrying heavy weights for a short distance. In all these instances, and I could mention many more, respiration does not flow in the usual rhythm. With people of this type altered respiration is one of the ways of giving expression to emotion. The nerve centres of vomiting and respiration lie close together in the medulla, and rapid respiration will relieve nausea, whereas it is aggravated by lessened and irregular breathing, thus slowing the reaction of one centre upon the other.

When an individual of this type is going to cross the Channel it may be noticed that as the boat train approaches the harbour he tends to become silent, or to express anxiety as to the condition of the sea, he will become, possibly, a trifle pale and have an altered look in the eyes, and his respiration, if it could be measured, would show that it has lost its easy rhythm. It is little wonder that he ascends the gangway (perhaps with a heavy suitcase in his hand to accentuate respiratory trouble) with the nausea of apprehension and excitement at his epigastrium, and that with the first few pitches or rolls of the boat, with consequent "catchings of the breath," his collapse is complete. The nausea of apprehension has been converted by the respiratory trouble into active retching or vomiting.

Sea-sickness is a complex in which various other nerve centres become involved ultimately thus the frequent retchings cause the entrance of bile into the stomach and gastric hyperacidity, resulting in vertigo and depression of the general circulation with all their consequences. There is no need to lay too much stress upon the action of the vestibular centre or upon altered blood circulation in the liver, as these are brought only into play after an attack of sickness has been excited. The vast majority of attacks commence before, or at latest as soon as the ship starts to pitch and roll and I have known of vomiting taking place before going on board. As one of your correspondents points out, sickness at sea and *mal-de-mer* are not necessarily the same thing, but the latter with all its graver symptoms is the follow-on of the former, if continued.

Proneness to the malady is, no doubt a very variable quantity but I am disposed to maintain that the onset of abnormal respiration is the determining factor. Persons endowed with sangfroid preserve normal respiration under all abnormal conditions and so escape sea-sickness, and are pronounced good sailors. However this gift occasionally

fails them during very stormy weather, and they become as other men. The recovery from sea-sickness after being at sea for a few days can be explained by the sufferer having, at last, acquired the art of maintaining normal free respiration under all conditions of sailing, and like most acquired rits, it is never quite lost again, but stands in good service in future voyages. In turn the self confidence gained hinders the onset of the nausea of apprehension—so fatal on starting a voyage at sea.

People who are prone to sea-sickness cannot do better than go below immediately after embarking, and lie supine in an airy cabin, or saloon, covering themselves with a rug to counteract the chilly feeling that generally precedes sickness. The pitch and roll of the boat is much less below deck. The eyes should be closed so as to exclude ocular impressions, and the mind should be concentrated upon the occupation of maintaining regular, normal breathing throughout all conditions of sailing. This course of action has a most calming effect upon both body and mind, and will secure a comfortable passage to many a sufferer. The tendency to gasp at every pitch and roll soon subsides, and the mind being usefully occupied dispels the nausea of apprehension. The supine position should be kept until the ship is really in calm water, or even until the anchor is cast, if the sea voyage be of a few hours' duration only. When the voyage is going to last for some days, rest in bed must continue until the art of breathing normally under all conditions has been acquired.

It is scarcely needful to say that individuals of the type referred to should take no food during the two hours before going on board, and, if the voyage be short, should continue to fast until on shore again.—I am, etc.,

Stroud July 23rd

J A BLAIN, M D, D Sc

PATHOGENESIS OF ACUTE PRIMARY GLAUCOMA

Sir,—The circulation of the blood in the iris in the intact eyeball of the pithed toad can be observed under the microscope.

The method consists in cutting away a portion of the upper jaw round the eyeball, reflecting the lower eyelid, and placing the toad on the stage of the microscope. A low power of the microscope can be used. Light is thrown through the edge of the eyeball by mirror and condenser. The inner edge of the iris can be focused and easily seen as adjacent to a blue violet colour in the pupil of the eye. The blood can then be seen circulating in the vessels of the iris.

The way is now open for direct observation and measurement of blood pressure along the lines indicated in the recent paper by Leonard Hill on the capillary blood pressure in relation to oedema and cerebral and intra-ocular pressure.—I am, etc.,

Halesowen Aug 7th.

JAMES M McQUEEN

ACUTE NEPHRITIS

Sir—In the report of the proceedings of the Section of Medicine, held at Cardiff on July 27th (*British Medical Journal*, p 298), the opinion is attributed to me that "acute nephritis" is "almost certainly" the result of a toxin. I did not say this, and I did not and do not think this. All the argument I offered indicates that physical causes, even in the non-pregnant as in the pregnant, play a much larger part in the genesis of "acute nephritis" than physicians of to-day conceive. Indeed, in considering the etiology of acute nephritis, in spite of the evidence, physical conditions are almost universally ignored. It is a curious fact that the effect of the passage of blood through capillaries, only possible in virtue of the existence and play of physical forces, recognized in the physiological class-room of some importance for the well-being of tissue cells, should, in the domains of medicine and obstetrics, whether at the bedside or in the *post-mortem* room, be so completely passed by.—I am, etc.,

R H PARSONS

* *British Journal of Experimental Pathology* 1923 vol ix p 135.

SHOCK IN BLACK RACES

Sir,—I would like to add my support to Dr S M Dickson's statement in your issue of March 24th (p 524). In my experience the black man stands surgical shock in a most remarkable manner. During the great war I had the opportunity of seeing large numbers of wounded Europeans, Indians, and Africans, and I would certainly place the African first as regards his powers of resistance to surgical shock. With medical cases the position is entirely changed, and if the patient is kept in bed for any length of time he gives in and dies.—I am, etc.,

N P JEWELL, FRCSL

European Hospital Nairobi June 20th

Obituary

GEORGE EDWARD WHERRY, M Chir, FRCS,

Consulting Surgeon Addenbrooke's Hospital Cambridge

The death of G L Wherry in Switzerland, where he had delighted to dwell, will recall then Cambridge days to many generations of men now immersed in life on less pleasant lines, and a number of active surgeons in London who have examined at Cambridge will feel regret for the pleasant and kindly host who always entertained them on the eve of their labours. In the middle of July he went abroad in good spirits, and, after staying on the way at Wiesbaden, reached Zeimatt, where he was suddenly taken ill with acute abdominal symptoms, and died, nine days later, on August 12th.

Born on December 31st, 1852, at Bourne in Lincolnshire, George Edward Wherry was educated medically at St Thomas's Hospital, taking the Membership of the College of Surgeons in 1873 and registering on February 10th, 1874 after reaching the age of 21, in the Medical School he was for a time an assistant demonstrator of anatomy. In 1874 he was elected house-surgeon to Addenbrooke's Hospital, a post then much sought after, as it was compatible with taking a degree at the University. He accordingly became a member of Downing College, of which he was, naturally much to his gratification, last autumn elected an Honorary Fellow in recognition of his long services to medical education in the University. During his three years at Addenbrooke's he had as fellow resident Dr William Fwart, and began a life-long friendship with Dr Henry Guillemaud, who has provided some of the information here utilized. In 1878 he took the degrees of B A and M B, and was nominated by Sir George Humphry as his deputy at the hospital. The next year was remarkable for a number of successes, he proceeded by examination to the higher degree of Master of Surgery (M Chir), changed after the war to M Chir, being the fifteenth to receive this degree, which had been established in 1862, took the final FRCS, and on November 24th was elected surgeon to Addenbrooke's, an additional surgeoncy having been found necessary. With the very short interval in 1878 he had therefore served the hospital for forty-one years when he retired in 1915 on account of age, and was elected honorary consulting surgeon. Soon after his appointment to the hospital he initiated an ophthalmic out-patient department, which became extremely popular. From 1884 to 1911 he was University lecturer in surgery, undertaking operative surgery and clinical instruction. After the death, in 1915, of Howard Marsh, who was professor of surgery from 1903 to 1915, no successor was appointed, and Wherry was a most efficient and popular supervisor of the surgical examinations until his retirement a year ago, when he was succeeded by Dr H B Roderick. On October 17th last the examiners who had worked with him spontaneously showed their appreciation by a testimonial and a friendly dinner in London, when he entertained them with a speech full of humorous reminiscences.

His medical writings, though neither voluminous nor very numerous, were of rather special interest, such as *Preventive Surgery* (1895), *Alpine Notes and the Climbing Foot* (1896), *On Spinal Growth* (1898), *Why both Legs are of Equal Length* (1901), *The Horns of Animals* (1902). Some of these were reprinted in *Notes from a Knapsack* (1909), with some general essays, including speculations

about the use of certain spiral horns for hearing purposes, the rising posture of ungulate animals, and the teaching manner. Others of his essays were on curious out-of-the-way subjects, such as "The ears of Buddha," and "Rings under the eaves of old houses" in order to fit the thutch-hooks to remove the thatch if the house caught fire. Charles Lamb was a special favourite of his, and in 1925 he edited a charmingly written and illustrated little volume, *Cambridge and Charles Lamb*, telling the story of six Cambridge Charles Lamb dinners, held between 1909 and 1914 at the first of which he was in the chair, and made a most admirable speech in the manner of Lamb. The volume also contains his accounts of George Dyer, the friend of Lamb and protégé of Dr Anthony Askew of William Freund, best known from Lamb's verse as "Dyer's friend" and of Charles Syle, who did much to start these Lamb dinners. An Alpine climber since 1890, he was on the committee of the Alpine Club and wrote in the *Alpine Journal*, his last contribution in 1925 was a sympathetic "In memoriam" notice of A. D. Godley, Public Orator at Oxford, his brilliant friend and companion on many climbing expeditions, both in the Lake District and in the Alps.

Wherry was tall, spare, and active, and to the last an enthusiastic walker. In his early days he was a runner, and indeed mentioned in his lectures how he once ruptured the quadriceps extension in a race. He was a genial and interesting companion, full of information about antiquarian and biographical history of Cambridge and the neighbourhood, well read, and apt at quotation. H. R.

SIR CHARLES BALANCE sends us the following tribute to his old friend.

George Wherry was my senior in the profession by a few years. When I was a student at St Thomas's Hospital I occasionally spent week-ends up at Cambridge, the attraction being a visit to the wards of Addenbrooke's with Sir George Humphry. Wherry was then assistant surgeon, and my friendship with him dates from these Cambridge visits. His personality was very attractive. He was shrewd, reserved, gentle, unselfish, self-effacing, and affectionate. The fairy queens that ruled his life were not the hussies—gain, fashion, pleasure, power—"to whose domain belongs the nether sphere, the fleeting hour." He let them go, without one envious sigh, one anxious scheme.

Wherry had a great interest in the progress of surgery, especially in his own university, but his thoughts on this subject were uttered only in the privacy of an after-dinner talk and in the presence of an appreciative friend. Even then his conversation was gay, modest and impersonal so that his hearer would hardly know that he was a surgeon living at Cambridge. I am convinced that had Wherry been attached to a London hospital his character and attainments in general learning would have won for him a high position in the profession of surgery. But Wherry was an English gentleman who played the game of life manfully.

Wherry possessed a great sense of humour. He was a charming host and his conversation, punctuated with wit and wisdom garnered from many sources was delightful to listen to. Seldom I think he was conscious of quotation from prose or poetry. His memory was so good that the illustration of an argument or a jest in this way came naturally to him. Well, for me Lucius is dead and I am a better man since I have had the privilege of claiming Wherry as a friend. Some men are remembered less for what they have done than for what they were. Their influence persists in the lives of those who knew them purifying motive and encouraging virtue. Such a man was my friend.

WILLIAM SMITH SYME, M.D., F.R.F.P.S.

Surgeon Glasgow Ear, Nose and Throat Hospital and Lecturer in the University of Glasgow.

We regret to announce the death of Dr W. S. Syme, son of Glasgow, which occurred at Abersoch, North Wales, where he was on holiday, on August 14th. He was well known in Glasgow as a specialist and university teacher in diseases of the ear, nose, and throat, and in Carlisle, where he had practised as a consultant for many years.

William Smith Syme was a native of Newfoundland and received his medical education at the University of

Edinburgh, graduating M.B., C.M. in 1891, and proceeding M.D. seven years later. In 1918 he was admitted to the Fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow. For some months after graduating he worked as an assistant in Crewe, and afterwards commenced general practice at Gamlingay, in Cambridgeshire. In 1903, however, he removed to Glasgow in order to bring himself more into contact with the scientific side of medicine, and, although he had not yet developed a decided preference for any specialty, he undertook a good deal of clinical work at the Ear, Nose, and Throat Hospital. Subsequently he resolved to devote himself to this branch, and practised as a consultant in Carlisle, and afterwards in Dumfries also, while continuing his work in Glasgow, where he made steady progress. In 1917 he was appointed surgeon to the Ear, Nose and Throat Hospital, and three years later he became lecturer in diseases of the nose and throat in the University of Glasgow, and surgeon for diseases of the nose and throat in the Western Infirmary, Glasgow. He was also consulting aurist and laryngologist to the Royal Hospital for Sick Children, Glasgow.

Dr Syme played an active part in professional affairs, notably on the scientific side. He was one of the founders of the Scottish Otological and Laryngological Society, and acted for many years as its honorary secretary and treasurer. In the British Medical Association he was honorary secretary of the Section of Laryngology at the Annual Meeting in 1922 at Glasgow, and a vice-president of the Section of Otology and Laryngology in 1924 at Bradford. He served also as chairman of the Glasgow Central Division from 1923 to 1925 and his colleagues in the Border Counties elected him an associate member of their Branch. A Fellow of the Royal Society of Medicine, he was, at the time of his death, president-elect of the Laryngological Section. He made numerous contributions to medical journals, and was the author of the well-known *Handbook of Diseases of the Nose, Throat, and Ear*, published in 1920. With his wide professional activities he found time also for the cultivation of other interests. He was a Fellow of the Royal Society of Edinburgh, and had been president of the Rnskin Society in Glasgow. His eldest son, Dr W. S. Syme, jun., has for several years been working with his father as an assistant in the Ear, Nose, and Throat Hospital and the throat and nose department of the Western Infirmary, Glasgow.

THE LATE DR W. J. HOWARTH

DR CHARLES PORTER, late medical officer of health, Johannesburg, sends us the following personal appreciation of Dr W. J. Howarth, of whom an obituary notice appeared in our issue of June 23rd (p. 1091).

Following so soon after the death of the late Dr James Wheatley it is sad to ask indulgence for a last brief tribute of warm regard and respect for another old and valued friend, the late Dr W. J. Howarth, ex-president of the Society of Medical Officers of Health. That friendship dated from 1905, when he worked with me in Stockport, both before and after taking his D.P.H. for nearly a year, whenever opportunity offered. His facility for making friends and his loyalty in keeping them, his notable ability and cheery keenness and confidence foreshadowed the rapid success and advancement which characterized his work in Bury, Derby, the county of Kent, culminating in his appointment to the City of London, and one hoped for further achievement and honours for him. But that has gone with him and while sympathizing deeply with those he has left and lamenting the long and distressing tragedy of illness which ended his fine career, one cannot help recalling in the circumstances Wordsworth's lines:

Why should we weep to sorrow cling
When thankfulness were best?

Dr JOHN WALTER MELVILLE who died at the Royal Southern Hospital, Liverpool, on July 22nd at the age of 24 after a short illness following an operation for appendicitis, was a native of Barrow-in-Furness. He received his medical education at the University of Liverpool, where he was also a student of dentistry and graduated B.D.S. with honours in 1926 and M.B., Ch.B. in

1927, having earlier in that year obtained the diplomas M R C S and L R C P. In October last he was appointed tutor in dental surgery at the University of Leeds, but, having a preference for general surgery and desiring to specialize in such work eventually, he relinquished this post to become resident house surgeon at the Royal Southern Hospital, Liverpool, where he was working at the time of his death. He was a member of the British Medical Association. Dr Melville was a keen student of literature and of the drama; he was devoted to all kinds of out-of-door exercise but particularly to the sea, having an intimate knowledge of ships and shipping, and showing considerable skill as a yachtsman. The interment took place at Rampside, near Barrow-in-Furness, on July 25th, the bearers being all members of the medical profession.

Dr ARTHUR DAVID YULE, who died at Airthroath on July 23rd at the age of 53, had been in practice in that town for about twenty-five years and had been medical officer of health since 1911. He received his medical education at the University of Edinburgh and University College, Dundee, graduating M B, Ch B Edin with honours in 1896 and B Sc in public health two years later. He was subsequently appointed house surgeon at Leith Hospital, and later became resident physician successively at Leith Fever Hospital and at the Paddington Green Children's Hospital, London, afterwards settling in Airthroath. There he built up an extensive practice and was appointed surgeon to the Airthroath Infirmary, becoming medical officer of health for the burgh seventeen years ago. He was a member of the British Medical Association. Dr Yule had recently been particularly busy in connexion with the epidemic of small-pox which had broken out in the town, and it is believed that the discharge of the specially heavy duty which this entailed was largely responsible for the onset of his illness. He is survived by his widow and three children. The interment at the Western Cemetery, Airthroath, on July 25th, was attended by a large number of the general public and of representative persons, including the provost and magistrates of the burgh.

Dr GEORGE OLIPHANT McKANE, who died at Cleethorpes on July 26th in his eighty-first year, had been in practice for nearly half a century, and retired only three or four years ago. A native of Hexham, he qualified as a chemist before beginning his medical studies at Newcastle-on-Tyne. In 1875 he obtained the diplomas L R C P and L M Ed and L R F P S Glas, and commenced practice at Byers Green, Durham, removing later to Leeds and subsequently settling in the Grimsby district. The last twenty years of his active life were spent at Waltham, near Grimsby, where he conducted a large country practice and held the appointment of medical officer of health to the Grimsby Rural District Council. Dr McKane was a man of strong personality, and possessed a cheerful and sympathetic disposition which made him a popular figure with the country people among whom he worked and whose confidence he enjoyed to a marked degree. He was for long a member of the British Medical Association. His two sons are both in the medical profession, and held commissions in the Royal Army Medical Corps during the war.

Mr WILLIAM MARSHALL OAKDEN, who died on August 12th in his 42nd year, and who had been medical superintendent of St Luke's Hospital, Lowestoft, for the past six years, was educated at the King Edward VI Grammar School, Retford, and the Nottingham High School, proceeding as a foundation scholar to Peterhouse, Cambridge, where he took first-class honours in the Natural Sciences Tripos. He then entered St Thomas's Hospital with a scholarship, and subsequently gained the Bristowe medal. In 1913 he graduated M B, B Ch Camb, and was admitted a Fellow of the Royal College of Surgeons of England, having obtained the diplomas M R C S and L R C P two years earlier. After serving as casualty officer, house-surgeon, resident anaesthetist, and clinical assistant in the ear department at St Thomas's he was appointed

resident assistant surgeon and surgical registrar at St George's Hospital. During the war he held a commission in the Royal Army Medical Corps, serving in the acting rank of major in Salonika as a surgical specialist. In 1919 he was appointed orthopaedic surgeon at Springfield Park Ministry of Pensions Hospital, Liverpool, and in the following year became senior assistant surgeon at Queen Mary's Hospital, Carshalton. On the inauguration of the Metropolitan Asylums Board in 1922 of St Luke's Hospital, Lowestoft, for the treatment of surgical tuberculosis in adults Mr Oakden was appointed medical superintendent, an office he held until his death. He was a Fellow of the Royal Society of Medicine, and an active member of the Norwich Medico-Chirurgical Society and the British Orthopaedic Association, and only a few weeks ago was elected chairman of the North Suffolk Division of the British Medical Association. At the interment, which was attended by a large number of his professional brethren and others, the Association was represented by Dr W. Tyson. A colleague writes: Oakden was doing excellent surgical work at St Luke's Hospital, and there is little doubt that his close application to the many-sided duties of the responsible post which he held had a deleterious effect on a constitution which did not appear too robust. When he could be induced to speak at a medical meeting he impressed those present by the soundness and wide range of his knowledge. Those who had the privilege of his friendship knew how loyal and straight he was in all his dealings and how behind his quiet and reserved manner was a rich fund of humour. He had a well stored mind, and found his chief recreation in books and in music. He will be sadly missed.

The Services

HONORARY PHYSICIANS AND SURGEON TO THE KING

THE King has approved of the appointment of Lieut Colonel R. McCarrison, C I E., and Lieut. Colonel W. H. Leonard of the Indian Medical Service to be honorary physicians to His Majesty, with the brevet rank of colonel, in succession to Colonel C. R. Bakhle and Major General A. A. Gibbs (retired). Lieut. Colonel G. D. Franklin, C I E., O B E., I M S., has been appointed honorary surgeon to His Majesty, with the brevet rank of colonel, in succession to Colonel R. W. Knox, D S O (ret.).

DEATHS IN THE SERVICES

Dr Henry Pottinger Keatinge, C M G, died at Regent Road, Jersey, on June 21st, aged 67. He was the son of General R. H. Keatinge, V C., and grandson of the Right Hon. Richard Keatinge, Judge of the Irish Probate Court. He was educated at Uppingham at Guy's Hospital, and at Durham University where he graduated with honours as M B in 1883, also taking the diploma of M R C S in 1883, and subsequently obtained the F R C S in 1893. From 1884 to 1889 he served in the Egyptian Army taking part in the Nile campaign of 1885, and in several other actions on the Egyptian frontier, gaining the Egyptian medal, with three clasps, the Khedive's bronze star, and the Order of the Osmanieh (4th class). In 1890 he was appointed to the Egyptian Government Medical School at Cairo, and to the Kasr el Ainy Hospital, of both of which he subsequently became director. In 1913 he received the C M G. During the war he was at the head of the Kasr el Ainy Hospital, was mentioned in despatches and received the Order of the Medjidieh (2nd class). He retired in 1919, when he was given the Order of the Nile (2nd class). He was a corresponding member of the Zoological Society, an honorary Fellow of the Royal Academy of Medicine in Ireland, a member of the Egyptian Institute, and of the Garick and Flyfishers clubs.

Colonel Robert Wallace Wright, C M G., Army Medical Service (ret.) died at Totton, Southampton, on June 20th, aged 64. He was born on October 5th, 1863, educated at St George's, and took the L R C P Lond in 1885 and the M R C S in 1886. Entering the army as surgeon on July 28th, 1886, he attained the rank of colonel on March 1st, 1915, in the long list of war promotions on that day and retired on March 14th, 1919, when acting as a D D M S. He served throughout the great war was thrice mentioned in despatches, in the *London Gazette* of June 15th, 1916, January 1st, 1917, and December 24th, 1917, and received the C M G. in 1917.

Lieut Colonel Walter Taylor Finlayson, DSO, Indian Medical Service, died on board the P and O *ss China* on June 10th. He was born on July 14th 1877, educated at Melbourne University and St Mary's Hospital, and took the M.R.C.S. and L.R.C.P. Lond in 1903. Entering the I.M.S. as lieutenant on January 30th, 1904, he attained the rank of lieutenant colonel on July 30th, 1923. He served in the recent great war and received the DSO on January 1st, 1918. He was in civil employment in the Jails Department in the Punjab and was on his way out from Fimlongh when his death took place.

Medical News.

LIEUTENANT COLONEL C. T. SAMMAN, R.A.M.C. (ret.), has been elected Master of the Society of Apothecaries of London for the ensuing year.

THE first National Glass Convention is to be held at Bournemouth from September 19th to 22nd, when there will be discussions on the organization of the glass industry and a conference on the legislation concerned. The programme of the conference may be obtained from Mr Geoffrey Marchand, V.A., Glass Manufacturers' Federation, Aldwych House, W.C.2.

A PUBLIC health congress and exhibition, organized under the auspices of the various associations representing municipal and other local authorities, will be held in the Royal Agricultural Hall, London, in the week beginning on Monday, November 19th, when the opening ceremony will be performed by Mr Neville Chamberlain, Minister of Health, who as president of the congress, will afterwards address the delegates. The congress is designed to bring together all public health authorities and all interested in social welfare work, and the organizing committee, under the chairmanship of Sir Frederick Mills, has secured the co-operation of many distinguished workers in the field of public health. Sir George Newman will give an address on the opening day on the purpose of the public health services. On the following day, Sir Walter Fletcher will discuss research in public health, and Mr C. Hubert Bond will deal with local organization for the prevention and treatment of mental disorders. On Friday, November 23rd, Dr W. M. Willoughby, medical officer of health for the City of London, will give an address on food protection, and on the same day Mr R. H. P. Orde, of the British Red Cross Society, will speak on the construction and equipment of hospitals. Housing, the smoke problem, milk supply, water supply, sewage, and town cleansing will also be discussed.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that an intensive course of two weeks duration will commence on Monday, August 27th, at the Queen Mary's Hospital, Stratford, E.1. Instruction will be given in all departments of medicine, surgery, and the specialties. Copies of the syllabus may be obtained from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1, who will also supply information concerning other forthcoming special courses.

THE fourteenth annual conference of the National Association for the Prevention of Tuberculosis, which is to be held in the British Medical Association House, Tavistock Square, London, on October 15th and 16th, will be attended by a number of Canadian medical officers who are visiting Europe to study tuberculosis work. Sir Arthur Stanley will preside and the principal speakers in the first day's discussion, on 'The occurrence of tuberculosis among primitive peoples,' will include Dr R. C. Ferguson (Saskatchewan), Dr Vassal (Annam) and Professor S. Lyle Cummins. The subject for the second day's proceedings will be 'The principles underlying a scheme of anti-tuberculosis measures in any country,' and the opening speakers will be Sir Robert Philip, Dr Howard Holbrook (Canada), and Dr G. Lissant Cox. A dinner in honour of the Canadian visitors will be given in the Savoy Hotel on the first day of the conference. The proceedings are open to all persons interested in tuberculosis, the fee for membership of the conference being £1. Full information may be had from the secretary of the Association, 1, Gordon Square, London, W.C.1.

Recently the association announced the publication of a new series of posters designed to assist organizations and individuals in anti-tuberculosis work. These posters are eminently suitable for display in schools, hospitals and dispensaries, public buildings and workplaces; most are printed in colour. Each embodies either a simple, direct message of advice on preventive methods or an appeal for support in the general campaign. A number of the posters have been prepared in postcard form. Another educational activity is the creation of a caravan service with three motor vehicles, each carrying a medical practitioner as lecturer,

with a cluoma, supplies of films, posters, charts, photographs, and other material for a small tuberculosis exhibition. These units are placed at the services of local authorities, etc., throughout Britain, and requests for co-operation will be welcomed. A booklet illustrating the association's posters and giving details of the caravan educational service may be had on application to the address given above.

THE total number of cases of paratyphoid fever under treatment in London on August 22nd was 119, fresh cases having been reported to the Metropolitan Asylums Board during the past few days from Kensington, Fulham, Lambeth, Lewisham, Islington, Shoreditch, Stepney, and Hackney.

WE have been asked to direct the attention of medical practitioners to an advertisement which appears in this issue relating to 'The Retreat,' a maternity home for unmarried mothers, with a baby home attached, owned by the National Free Church Women's Council, but in practice non-denominational. The home is conducted in accordance with the requirements of the Ministry of Health, from which it receives an annual grant. Girls are expected to remain in the home for at least six months, and nuptial fees are charged. Full information may be obtained from the Superintendent, 19, Ross Road, London, S.E.5.

THE July issue of the *Kenya and East African Medical Journal* contains a report of an investigation into animal nutrition in Kenya, the supervision of which was undertaken by Dr J. B. Orr, director of the Rowett Research Institute, Aberdeen. One conclusion reached was that, in areas where the pasture is deficient in minerals, an increased rate of growth in lambs and calves, and a better yield of milk in cows, can be obtained by feeding with appropriate mineral mixtures. The issue also contains an article on the control of billharzia disease, by Dr T. G. Cawston, and an account by Dr A. R. Paterson of the organization of antimalarial work in the Federated Malay States.

THE Ministry of Health has issued a circular (No. 911) referring to the scheme for the investigation of the causes of maternal death outlined in Circular 888, of which a summary was published in the *Journal* of April 28th (p. 729), and stating that the Minister understands that some maternity and child welfare authorities are in doubt as to how they can obtain particulars of maternal deaths occurring in their areas. It is pointed out that under Section 28 of the Registration of Births and Deaths Act, 1874, a sanitary authority can obtain from the registrar, on payment of the prescribed fees, returns of such particulars, which, it is understood, may also be obtained by a county council. The circular suggests that each local authority whose medical officer of health has undertaken responsibility for this investigation should make the necessary arrangements with the registrars in their areas.

AN appeal has been issued for support for the Incorporated Soldiers and Sailors' Help Society. Founded thirty years ago, the society has been faced with heavy responsibilities, particularly since the war, when it organized the Lord Roberts Memorial Workshops to provide for the training and employment of disabled ex-service men. In addition, large numbers have been helped with grants of money or clothing, or with work, or otherwise, and in all assistance has been given to over 900,000 ex-service men. The society depends entirely upon the response to its own appeals, receiving no assistance from any other organization. Donations should be sent to the chairman, Countess Roberts, at the head quarters of the society, Room A 122, Brompton Road, S.W.3.

Paton's List of Schools and Tutors, the thirty-first edition of which has just been issued, is intended to assist parents in the choice of schools suitable to their location, their preference in educational methods, and their pockets. Each school is included in a classified list and is also the subject of a brief descriptive note. The work also contains a list of scholarships and exhibitions, and a series of articles dealing with the preliminary educational requirements of the various professions and of certain other callings, with information regarding the prospects they offer. The price of the book is 5s. Copies may be consulted at many libraries and clubs in England, India, and the Dominions, and at British embassies and consulates abroad.

THE second issue of *Leprosy Notes*, published quarterly by the British Empire Leprosy Relief Association, opens with an account by Dr E. Muir of the organization of the campaign against the disease. Dr Muir also contributes a note on the use of potassium iodide in leprosy, while Sir Leonard Rogers discusses the bearing on prophylaxis of recent advances in treatment. Dr E. A. O. Travers describes the Tal Poong Choo treatment, which he states has been successfully employed for some years at the leprosy asylum at Kuala Lumpur. Tal Poong Choo is the Chinese name for *Hydnocarpus anthelmintica*, which is given in the form of a powder, with a small quantity of cannabis indica. Other articles deal with leprosy in the Southern Sudan, in Uganda, in the West Indies, and in India.

PROFESSOR FRANCIS DE TORDAY who is senior physician to the children's State asylum in Budapest has published a pamphlet entitled *Science of Disease in Childhood and the Protection of Children in Hungary*, which gives an account of the hospitals and other institutions concerned with pediatrics in Budapest and elsewhere in Hungary. The pamphlet contains also a description of the methods taken with regard to child protection in that country. It is published by the Royal Hungarian University, Budapest.

DR. HERMANN LUDWIG, professor of gynaecology at Erlangen, has been nominated an honorary member of the American College of Radiology, and Dr. Erlo Hoffmann, professor of dermatology at Bonn, has been nominated an honorary member of the Spanish Dermatological Society.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561 9562 9563** and **JOG 1** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are **EDITOR of the British Medical Journal, Antology Westcent London**.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.) **Articulate Westcent London**.

MEDICAL SECRETARY, Medicine Westcent London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams **Basillus Dublin** telephone 62550 Dublin) and of the Scottish Office 7 Drumsheugh Gardens, Edinburgh (telegrams **Associate, Edinburgh**, telephone 24361 Edinburgh).

QUERIES AND ANSWERS

OBSTETRICAL FORCEPS

"T. E." asks where the original descriptions can be found of Barnes's and Denman's obstetrical forceps.

Mr. C. J. S. Thompson informs us that Thomas Denman first described his forceps in his *Introduction to the Practice of Midwifery* at page 357 of the 1835 edition. Robert Barnes originally described his instrument in his *Lectures in Obstetric Operations*, 1870 vol. I, p. 10.

CHRONIC GLOSSITIS

"N. B." would like suggestions for treatment in a case of chronic glossitis (two and a half years duration) in a young married woman of 30, the usual remedies including no autogenous vaccine made from *B. coli streptococci Staphylococcus albus* and aureus—these organisms having been found in the intestine—failing to give any relief. The patient who is slightly neurotic had an attack of cystitis due to *B. coli* over six years ago. There is no specific trouble.

RATE OF FLUID ABSORPTION BY THE BODY

Dr. T. H. Bishop (London) writes in reply to Dr. A. H. Skinner's inquiry (August 4th, p. 227) regarding the absorption of fluids under the skin and into the peritoneal cavity for the purpose of replacing the fluid loss in cholera. He may be interested to know that I employed the intraperitoneal route for saline perfusion during cholera epidemic work in Bengal from 1910 to 1914. Using a special trocar cannula I found it possible to introduce from sixty to one hundred ounces in from ten to fifteen minutes. The rapidity of absorption could be noted by the early return of the peripheral pulse, which frequently happened in favourable cases before the entire quantity of the fluid had entered the cavity. Hamburger has shown (and I was able to confirm this observation) that absorption by the peritoneum in the case of a healthy dog goes on after death. The technique of perfusion is simple—it was used successfully by the staff of assistant and assistant surgeons working with me—but to minimize the risk of injury to the intestine it is best to perform the necessary puncture of the abdominal wall while fluid is issuing from the cannula. I came to regard the intraperitoneal as equally effective with the intravenous route in the type of case where fluid loss was the principal feature—there was the added advantage that, if fluid

replacement was going to succeed one perfusion operation was sufficient. I first used hypertonic saline solution but believing that the greater concentration caused much of the discomfort which followed I later adopted Locke's solution, and think that this gave as good results without the same amount of discomfort. The method was described in the *Indian Journal of Medical Research* (October 1913) and the trocar-cannula used was made from my design by Messrs. Smith, Stanstreet, Ltd. of Calcutta. Starling's Fluids of the Body is very useful in the study of absorption problems.

INCOME TAX

Expenses of American Tour

We have been asked whether the expenses of the surgical tour in Canada and the United States which was referred to in our issue of February 4th last can be treated by members of the party as expenses admissible for income tax purposes in calculating the liability of their respective firms.

The tour seems to have been mainly or entirely for educational purposes though perhaps it may have served subsidiary purposes also. On that basis the expense would seem to be somewhat analogous to that incurred in taking special post-graduate courses and could not properly be regarded as incurred wholly and exclusively in carrying on the work of the practice. We regret that we cannot find adequate grounds on which to advise that a claim for the allowance of these expenses can be made good.

National Health Insurance Fees

"G. C." writes to say that an Inspector of Taxes has applied to the clerk to an Insurance Committee for particulars of the amounts paid as capitation fees to a certain doctor. Can the request be enforced?

In our opinion the relationship of employer and employee does not exist between the Insurance Committee and the medical men concerned, and on that basis the request is not enforceable as the statutory power which the Inspector quotes is not applicable.

LETTERS, NOTES, ETC.

MEDICAL TREATMENT IN CHINA

Dr. G. DOUGLAS GRAY (Chalfont St Giles) writes: Probably the two answers to Fleet Surgeon Home's inquiry as to retaining fees being non-payable during illness in China may be sufficient but as this cannot have been very frequently quoted may I be allowed to add that I never found any evidence of it during my long residence as medical officer to H. B. M. Legation in Peking. In my official capacity I had to collect information, conditions of practice etc. from medical practitioners all over China and no Chinese or foreign doctor had any acquaintance of contracts which ceased when their Chinese patients fell ill.

TREATMENT OF ECLAMPSIA

MAJOR FLEMING GOW I.M.S. asks us to correct the last sentence attributed to him in the report of the discussion on eclampsia in the Section of Obstetrics and Gynaecology of the Royal Society of Medicine (*Journal* June 23rd p. 1066). He stated that he had 'practically given up Caesarean section for eclampsia unless there was also present some definite indication for that operation such as the under-developed pelvis which was frequently found in primiparae aged 13 or 14 in Bengal.'

MOHAMMADAN PILGRIM SHIPS

Dr. K. SHALLCROSS DICKINSON (Sandertand) writes with reference to the inquiry of 'Port Said' (May 26th, p. 930), and the reply published on August 4th (p. 223). A friend who is engaged in carrying pilgrims from the Dutch East Indies to the Straits Settlements in ships belonging to the three companies, informs him that the scale of normal daily rations laid down by the Dutch authorities is ample care is taken to secure for each pilgrim plenty of food ventilation and about 20 square feet of space. Bathroom and lavatory accommodation is adequate and is kept clean and all open decks are covered with awnings. Each ship carrying 1,000 or more must be provided with two doctors and all medicines are issued free of cost. The sick can have medical attention at any time of the day or night and beyond the official inspection every morning the doctors are expected to pay visits at intervals during the day. Dr. Dickinson's correspondent states that he has never seen any harsh treatment of pilgrims by ship's officers. Most of the deaths occur among the old people in consequence of senile decay, and the mortality appears to be rather higher on the return voyage owing to the arduous nature of the pilgrimage apart from the sea voyage. He suggests that the same conditions probably prevail generally as regards pilgrims travelling from British Indian ports and that such neglect as was mentioned by 'Port Said' should be reported to the Consular and Board of Trade authorities.

VACANCIES.

NOTIFICATIONS of offices vacant in universities medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 36 37 38 39 42 and 43 of our advertisement columns and advertisements as to partnerships assistantships, and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 193.

EDUCATIONAL NUMBER. SESSION 1928-29

THE ART AND SCIENCE OF MEDICINE IN RELATION TO PROFESSIONAL TRAINING

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.,

PROFESSOR OF MEDICINE, UNIVERSITY OF BRISTOL, PHYSICIAN AND DEAN OF FACULTY, BRISTOL ROYAL INFIRMARY

THE late Professor Kanthack, in an address delivered thirty years ago before the Alcornthian Society of St. Bartholomew's Hospital, spoke of the coveted goal of medicine as being its establishment as an exact biological science. Medicine might, perhaps, be easier to teach if it ever became an exact biological science, it would certainly be easier to practise if a doctor's duty were performed according to the ascertained rules and laws of an exact science as an astronomer applies known rules and laws. The lawyer is judged by the virtue of his pleading not by the issue of the cause, he may gain success where he fails to gain a verdict but the physician as Bacon said, "hath no particular acts demonstrative of his ability, but is judged most by the event" (or result). Dr. PIERCE, in his presidential address read before the Institute of Medicine of Chicago in December, 1927, summed up the competent physician as "a man who, with a background of science practises an art that he has gotten through technical training."

RESEARCH AND PRACTICE

The doctor differs from most other craftsmen because he is expected to discover the scientific laws underlying his craft as well as to apply them in practice. Discoveries in the science as well as in the art of medicine are commonly made by men who have been trained for the practical craft of medicine. There have been conspicuous exceptions, notably Christopher Wren, who, becoming interested in medical problems through his connexion with the Royal Society, made the first intravenous injections of drugs in animals for the purpose of observing their effects and also performed in a dog the first splenectomy. Pasteur came almost accidentally to human diseases from his researches into brewing and wine making. Jesty, the Dorset farmer noticing how milkers were rendered immune from small pox, practised systematic inoculation with cow-pox with such success that Jenner was led thereby to the introduction of vaccination.

The advancement of medical knowledge cannot, however depend solely upon such windfalls from outside the ranks of the profession therefore medical education must be planned on broad enough lines to give a common starting-point for the researcher as well as for the practitioner. Nor is the role of the practitioner at any time so completely separated that he may not, whilst engaged in practice, make discoveries that place him among the researchers. The converse unfortunately is less likely to happen, laboratory research may so engross the attention that the research worker may seek no further experience in the

practice of medicine. On the whole, the advantage is with the practitioner, for he can never abandon wholly the experimental method, nor need he cease to enlarge the boundaries of his own knowledge because he is observing the responses of human beings rather than those of guinea pigs.

THE PURPOSE OF A MEDICAL TRAINING

When a medical student is first qualified he has to recollect what he has learnt of the experience of others but presently he must rely on his own and he soon finds that experience must be actively gained, it does not fall into the lap unsought. The policy of "wait and see" does not succeed so well as that of "look and see." The purpose and design of the medical curriculum is to train the student partly in the science of "looking and seeing" and partly in the craft or technique of "doing." Or should one say the *art* of looking and seeing? For surely it is in a manner an artist's gift to be able to see clearly or as Dr. John Brown expressed it "all primary discoveries are made by men who are artists in the sciences in which they work."

It is a defect in our whole education that the artist's sense is deliberately repressed, the prizes tend to go to possessors of superior memories rather than to those who can observe and reason best. Matters are perhaps not quite so bad as when Swift could write

Our knowledge is but mere remembrance all
Remembrance is our treasure and our food

And Dugald Stewart had the courage to speak even plainer. "Those men," he wrote, "who are possessed of a memory for detached and insulated facts are very seldom distinguished by the higher gifts of mind. Men of little ingenuity seldom forget the ideas they acquire because they know when an occasion occurs for applying their knowledge to use they must trust to memory and not to invention."

PRELIMINARY STUDIES

Modern education and even medical education is beginning to set less value upon overloading the memory with unrelated and undigested facts than formerly. Epictetus long ago compared the memorizing system to the behaviour of sheep who after they had been feeding should prevent their shepherds with the very grass itself which they had cropped and swallowed instead of concocting it into wool and milk. The elementary sciences the pre-medical subjects of chemistry physics biology and botany are in the curriculum to familiarize the student with the structure

and behaviour of the materials with which, and upon which, he will have to work, also with the instruments that will aid him in his task. The student passes from generalized studies to a particularized study of human structure and function in anatomy and physiology, together with the chemistry and physics of living tissues. The main object of these studies is to train the eye to observe, the mind to reason, and the hand to act, though there is a danger that the intervention of examinations may obscure this object. Anatomy, above all other subjects in the curriculum, may be so taught as to become a matter of memory and nothing else. It is possible for a student with a retentive memory to gain the approbation of teachers and examiners by the very methods that would have caused the shepherds to slaughter Epictetus's sheep out of hand.

CLINICAL EDUCATION

The clinical portion of medical education embraces a somewhat different plan. The problems are the diagnosis of diseases, their prognosis, and treatment, or, better still, their prevention. An entirely new factor comes into play. Hitherto the student has been set the task of investigating the behaviour of materials by observing objective signs, his studies of human patients must include the interpretation of symptoms—that is, of discomforts and pains experienced and complained of by the patient. The interpretation of signs might conceivably become an exact biological science, but any scientist would justifiably reject the results of an experiment which involved so large a contribution of personal error as the description of symptoms given by an average patient. The marvel is not that doctors sometimes misinterpret symptoms, but that they ever learn enough of the art of happy guessing to come to any correct conclusions. Sometimes the symptoms or sensations of the patient are so unequivocal as to leave scarcely any margin of doubt. Sometimes there are objective signs which, taken in conjunction with the symptoms, lead to a correct conclusion.

In the interpretation of symptoms collective experience of the past, and especially records of post-mortem examinations, have their greatest value. In the interpretation of signs every artificial means of improving the instruments of observation must be welcomed. It is not so very long since the methods of diagnosis consisted in listening to the patient's account of his symptoms, looking at his tongue, feeling his pulse, and perhaps inspecting his urine. Slowly new methods forced their way in, each in turn meeting with some opposition. Auscultation and percussion have been in use for little more than a hundred years, the use of the clinical thermometer is not so old, all that is embraced in clinical pathology dates back at most some fifty years.

MEMORY, OBSERVATION, AND REASONING

Nowadays to probe deeper into Nature's mysteries of health and sickness the student must spend many hours, not in memorizing all the wisdom of the ancients, but in learning to use the tools of a calling in which every craftsman must observe for himself. Still there hangs over him the threatening storm-cloud of examinations. Tradition adds to the terror by persisting that examiners in clinical subjects prefer feats of memory to proofs of ability to observe accurately and reason clearly. Any accurate observer can be trusted to amass a useful store of experience, no store of remembered facts can come to the rescue of inaccurate observation. It is of little use knowing how to perform a given operation if the skill to perceive the need for the operation is lacking.

Medical education seems to the beginner to waste a great deal of time in the preliminary sciences, but their study involves the use of a large variety of instruments of precision: it imparts accuracy to the organs of perception, and trains the mind to logical reasoning. Clinical medicine demands the use of many instrumental aids to the organs of perception. The extremest and simplest illustration of their use lies in *x* rays, without which the eye of the keenest observer would be blind. The medical student then must learn by constant practice the operations of surgery, how to employ the stethoscope, laryngoscope, ophthalmoscope, cystoscope, and any other instru-

ments which represent to the doctor the telescope of the astronomer. Moreover, he must, in addition, use the microscope and the test tube.

BEDSIDE AND LABORATORY

At present there is a passing struggle over the place of laboratory work in the clinical curriculum. The struggle will pass as all previous ones have done, and the student of two generations hence will marvel to hear that the laboratory was ever kept at arm's length from the bedside. But the discoveries of one generation are the common places of the next, so that, as Courdoret phrased it, "two years employed under an able teacher carry the student beyond those conclusions which limited the inquiries of Leibnitz and of Newton," a truth which the teacher of clinical subjects occasionally overlooks. The student grows impatient of the "barrack square" drill which the time-honoured methods of inspection, palpation, percussion, and auscultation embody; he asks whether the *x* rays have not superseded this load-carrying labour. The teacher who insists on the old methods must be sure of his reasons for preserving the handicraft after the introduction of machinery.

After obtaining a qualification the newly fledged doctor makes his choice of practising his profession directly upon the actual patient or more indirectly by studying the general problems of the healing art without reference to individuals. In common parlance he must become a practitioner or a laboratory worker—although the distinction is inaccurate. Let some such distinction be dictated by purely economic considerations. Mere lack of time is one great economic force which separates the bedside worker from the laboratory worker. The former must listen to the patient's talk, and while the patient is talking the worker in the laboratory can go on unhindered thereby. It is not so much a difference in scientific method that distinguishes them as a different distribution in their fields of endurance. The laboratory worker is a patient watcher of tubes and Petri dishes; the physician a patient listener to the human voice, the surgeon adds thereto a patience in handiwork, and the obstetrician a mighty patience with the works of Nature.

The branch of medicine which the doctor decides to follow is often dictated by opportunity. Sometimes the decision is due to an evaluation of talents made by the individual or the teacher, sometimes it is arrived at by exhaustion of a particular field or fields of patience. Beyond and above these there exists in some natures a strong urge towards personal service, which seems to make direct contact with the patient imperative. Such natures are not inspired so keenly by the spirit of serving humanity in the abstract as by the sight of the individual imploring their aid.

THE VALUE OF A COMMON CURRICULUM

But for all these ultimate destinations the medical curriculum starts on the same lines and continues on the same lines up to the point of qualification. It is better that it should be so than that choice of diverse roads should be offered too soon to the undergraduate student. If the choice could be made too early the danger might arise that some part of medical practice would be relegated to an inferior caste of craftsmen with a shortened course of training.

Economic pressure occasionally brings out complaints that doctors ask too high wages, sometimes there seems a risk that "approved societies" might be content with, or even demand, something less than a full training for "panel practitioners." The like has happened before in the history of medicine when the monkish physician, despising the surgical handicraft, made over the surgical part of medicine almost entirely to the barbers. Fortunately the jettison was never complete, Henry of Mondeville, Guy of Chauliac, and John of Arderne helped to keep human surgery from falling to the level of saw-golding. It will be a sorry day if the education of the medical student divides too soon, so that the training for general practice becomes divorced from the training for research work.

This strange medley of a curriculum is worth retaining if it can give in our own time a Lister, a Hughlings Jackson, a Michael Foster, and a James Mackenzie.

THE ART OF STUDY ITS PRINCIPLES AND THEIR APPLICATION

BY

R D GILLESPIE, M D, M A C P D P M,
PHYSICIAN FOR PSYCHOLOGICAL MEDICINE OVA S HOSPITAL

STUDY, even of the sciences, is an art. But it is a lowly form of art, being with most of us a means to an end, and not to be pursued for its own sake. It is therefore desirable to make use of whatever general principles may increase our studious efficiency. Naturally, psychology is appealed to as the appropriate body of knowledge from which to derive such principles, and it may be of some interest and practical utility to set forth briefly the experimental and other psychological data whose interpretation may facilitate study. The data are not many, the deductions are neither of great value nor very novel, but they have some intrinsic interest, as well as one or two practical applications.

The problem of efficiency in study can be attacked from two sides—the subject-matter, and the mental processes involved. The latter alone can be dealt with here, the interest of the subject-matter depends upon its content and the manner in which it is presented by its professors.

THE MENTAL PROCESS

The mental process involved in study is, strictly speaking, a unitary whole, but several aspects of the process may conveniently be distinguished, these are principally attention, memory and association.

In considering, first, the mental process in its entirety, study may be regarded as a form of "mental work." Experimentally a "mental work" curve has been obtained from a simple task, like adding figures continuously. There is at first a general, but very irregular, tendency for a rise to occur in the number of figures added per unit of time, followed by a decline in the number added. Several factors are at work in producing such a complex curve. The influence of practice, which is most marked in the beginning and should lead to a gradual and continuous rise, is soon interfered with by fatigue. The latter is a complex affair, and its particular nature depends largely on the kind of task involved. Probably very little of the fatigue that appears in every mental task is actually mental in origin. In writing down additions, for example, there is the digital muscular fatigue, in reading there is ocular fatigue and so on. Much also of what masquerades as fatigue is the result of distraction—other objects attract the attention, and the main performance is interfered with. This is well exemplified in the difference in the amount of work done on a task that is of itself interesting, and on one that is merely boring.

Distractions operate much more readily in the latter case and reduce the output, thus simulating the effects of fatigue. But it is possible that a certain minimal amount of distraction is beneficial in increasing the mental output over short periods. For example, persons working an ergometer (against a load of one kilogram) with their upper limbs, and adding columns of figures at the same time were found in some instances to perform more work of each kind (mental and muscular) than when doing either kind alone. An illustration of the comparative indefatigability of mental performance as contrasted with physical performance was furnished by the feat of Dr Arai who multiplied pairs of four-place figures (for example, 2,738 × 4,912) continuously for twelve hours without a break. At the end of twelve hours of continuous multiplication she took rather more than twice as long to perform each complete four figure multiplication as she did at the beginning. Her efficiency was therefore still very high, as even at the end she was performing a feat which probably could not be equalled by two persons out of a thousand engaged in mathematical work" (Watson). Furthermore a normal

period of sleep completely restored her capacity, the work being repeated on four successive days.

Fluctuations in the rate of improvement in any mental performance take place in other ways. We may improve for several days at some task, and then fail to make any progress for a time after which the improvement may be resumed. It is quite likely that subconscious rearrangements have been occurring, which when they are completed, enable further improvement to take place. "Spurts" also occur, notably at the beginning, when the novelty of the task engages all the mental energy and at the end when the prospect of the satisfaction of a completed task is accompanied by increased attention to it—interest being the essential factor in both these instances.

There is another factor called "incitement" or the "warming up" that occurs as the task proceeds. It is as if our mental machinery had a degree of inertia which can be overcome only gradually. Hence the importance of continuity of working and the avoidance of outside interruptions. To be called away to a telephone even for a few minutes causes a greater loss in efficiency than is indicated by the mere loss of time, the output of work immediately after such an interruption is less than the output immediately before.

On the other hand it is found to be beneficial if brief "rest pauses" are introduced at considerable intervals during long periods of work. In this way, not only mental work may be made more efficient, but the output of factories has been favourably influenced. In a sweet manufacturing factory, where the working conditions were investigated by the National Institute of Industrial Psychology, an increase in output of 5 per cent was produced simply by the introduction of a few rest pauses at definite times in the working day. In a well known group of restaurants, the curve of breakages rose steeply in the late afternoon. By the introduction of a rest pause of about fifteen minutes duration at 3 p.m. the curve was flattened to an almost horizontal line.

It is usually considered that to transfer one's attention to another task after feeling "fatigued" at a previous one is efficacious in restoring mental efficiency. "Change of work is as good as a holiday" is an almost proverbial saying which is in part confirmed and in part controverted by experimental evidence. The so-called "subjective fatigue" (which is another name for boredom) certainly tends to be abolished in this way. There is some statistical mathematical evidence that a person readily bored by prolonged continuous work of one kind is likely to be similarly affected by continuous work of any kind—a conclusion which hardly requires such elaborate proof.

Two kinds of "objective fatigue" have been distinguished—specific and general. Specific objective fatigue as the name implies is not transferred from one operation to another—that is a change in the type of work abolishes it, but in a given individual it is apt to appear specially in a certain type or in certain types of mental work. General objective fatigue—a fatigue which having been induced by one type of operation persists after a change has been made to some other kind of work—may account for from 5 to 25 per cent of the total fatigue that is only 5 to 25 per cent of the original efficiency cannot be restored by a mere change of occupation (Spearman).

Several general deductions can be made from the experimental results that have been summarized. Mental fatigue is a matter of comparative unimportance. Only a small proportion of it (general objective fatigue) is probably attributable to cerebral activity. Even this proportion is readily abolished by a rest pause or by normal periods of sleep. The greater part of "mental fatigue" is made up of boredom (for which there are obvious remedies) or by

the so-called "specific objective fatigue," which is surmounted by changing over to another type of mental activity—for example, so simple a change as from the multiplication to the cancellation of numbers. Clinical experience bears out these experimental findings. "Mental exhaustion," "brain strain" from "overwork," and the like can be safely discarded as a hypothesis in 999 out of 1,000 cases. The apparent mental incapacity in such cases is nearly always the result, not of intellectual effort, but of anxiety or a kindred emotional disturbance, resulting from preoccupation with some personal problem. This is brought home very dramatically in the sudden recovery of persons complaining of "brain-fag," which has perhaps limited their work to periods of less than an hour each, when a source of worry is removed. For practical purposes the mind is almost tireless. On the other hand, violent physical exercise disables a person from concentrated mental work for some time afterwards. Even when there is considerable deprivation of sleep, intellectual accomplishment may be persistently maintained at a high level if the worker does not worry about his insomnia.

Another and a very obvious deduction from the experimental work is the desirability of arranging work in such a way that it can be carried on without interruption for several hours at a time if need be. "Warming up" can then occur to the full. Much the most difficult part of any study is the beginning of it. At the same time, a judicious arrangement of "rest pauses" (which need only be very brief) increases the total mental output. The loss of "interest" with such short pauses is not great. The distribution and length of the pauses has to be worked out empirically by each individual for the type of work that he does.

MEMORY AND ATTENTION

So much for the total mental process. We may now turn to some of its aspects. Memory is one of the most important aspects of the mental process involved in study. There are three distinguishable stages in memory—namely, the impression of an experience on the mind, its retention there, and its recall when wanted. It is convenient to consider these separately and to examine their conditions.

A very important factor in the impression or registration of an experience is the nature of the subject matter (its lucidity, etc.), but our present concern is with the most efficient mental attitude. It is well known that the clearness of our impressions depends largely on our attention to the objects producing them. The field or range of attention can be regarded as having a focus or central "area," and a margin. Objects in the focus of attention are more clearly perceived than objects in the fringe or "marginal field" of attention. This fact is very well established. Nevertheless it is interesting to know that objects in the fringe or margin of attention are sometimes much more distinctly and firmly impressed than at first seems credible. Thus Dr Morton Prince's subject, B. C. A., looked into a crystal (a method of bringing focal attention to bear on experiences originally in the "fringe"),

and saw there some printed words which had no meaning for her whatever and awakened no memory of any previous experience. It was afterwards found that the words represented a cablegram message which she unconsciously overheard while it was being transmitted over the telephone to the telegraph office by my secretary in the next room. She had no recollection of having heard the words as she was absorbed in reading a book at the time. The correctness of the visual reproduction is shown not only by the automatic writing (another method of recalling marginal impressions) which remembered and recorded the whole experience, but also by comparison with the original cablegram.

For ordinary purposes, however, the majority of us cannot rely on anything but focal attention. Ability to attend persistently seems to be directly proportioned to the degree of intelligence possessed by the person attending. Extreme instability of attention is a symptom in mentally defective persons. By experiment it is found that a lapse of attention, usually unnoticed, occurs in normal persons every few seconds. For example, if a watch be placed just within hearing, it is found to become alternately audible and inaudible. Fatigue and alcohol increase, while bromide is said to diminish the depth and duration of these lapses. Any toxæmia besides alcohol, and organic brain disease,

have a similar effect in producing frequent and prolonged lapses of attention. This increased fluctuation of attention, or "mental-tension defect," is a useful diagnostic sign. It helps also to account for the greater difficulty in studying experienced after a meal with which alcohol has been taken.

Useful attention—that is, attention to the task in hand—is disturbed more often by preoccupation with other interests than by any other cause. "Single mindedness" is essential for efficient work of any kind, and certainly not least in studious occupations. Where persons (n. s.) suffering from organic brain disease and demonstrable toxæmia complain that their concentration is very bad, it is usually safe to reply that, on the contrary, it is very good, but it is directed faultily towards some personal source of worry.

The second, and more exclusively memorial, aspect of memory process is the retention of an impression on the mind. James considers retentivity to be immensely important.

"The persistence or permanence" of impressions "is a physiological property of the brain tissue of the individual, whilst their number is altogether due to the facts of his mental experience. Let the quality of permanence be called physiological retentiveness. This tenacity differs enormously from infancy to old age, and from one person to another. Some minds are like wax under a seal—no impression, however disconnected is wiped out. Others like a jelly vibrate to every touch but under usual conditions retain no permanent mark. Those latter minds, before they can recollect a fact must weave it into their permanent stores of knowledge. They have no *desultory* memory. Those persons on the contrary, who retain names, dates, and addresses, anecdotes, gossip, poetry, quotations and all sorts of miscellaneous facts without an effort have *desultory* memory in a high degree. No one was probably ever effective on a voluminous scale without a high degree of this physiological retentiveness. In the practical as in the theoretic life, the man whose acquisitions stick is the man who is always achieving and advancing whilst his neighbours, spending most of their time in relearning what they once knew but have forgotten, simply hold their own. A Charlemagne, a Luther, a Leibnitz, a Walter Scott any example in short of your quarto or folio editions of mankind must needs have an amazing retentiveness of this purely physiological sort. Not that mere tenacity will make a man great. It must be coupled with great passions and great intellect besides."

Imbeciles sometimes have an extraordinary, and extraordinarily limited, memory. Forbes Winslow (quoted by Tiedgold) mentioned the case of a man who "could remember the day when every person had been buried in the parish for fifty-five years, and could repeat with unvarying accuracy the name and age of the deceased, and the mourners at the funeral. But he was a complete fool. Out of the line of burials he had not one idea, could not give an intelligible reply to a single question, nor be trusted to feed himself."

Mere memory, then, in the sense of physiological retentiveness, is not enough. To have it in high degree is a great asset, but unless its stores are utilizable in an intelligent way, a phenomenal memory is of little help and may even be a hindrance. It is nevertheless natural to inquire whether this native retentiveness can be improved in any way. James holds that it cannot. McDougall thinks he has proved that it can be improved by repeated exercise, but the improvement he claims is slight of the best.

Experiments on the power of retention in normal individuals yield some interesting results. The experiments have principally been performed with series of nonsense syllables (that is, syllables like "rel," "tes," "bup"), because this is the simplest material for testing pure retention, and the least likely to be complicated by other functions, such as associations of ideas. If a series of, say, sixteen such syllables has been completely learned, a "curve of forgetting" is obtained. Two things can be observed from such a curve that it falls off at first very rapidly and then much more slowly so that nearly 50 per cent of what has been learned is lost in the first hour, but only a further 16 per cent at the end of a day and a further 14 per cent (80 per cent in all) at the end of a month.

Evidently, therefore, so far as this experiment goes what we have learnt within the last few hours benefits us little more than what we learnt twenty-four hours or even many days ago. Superimposing two curves, one twenty-four hours older than the other we obtain a comparatively slight difference in the quantity retained after twenty-four

hours. Hence it would appear that the last night's cram before an examination is of little benefit. Unless for the acquisition of entirely new material, we lose comparatively slightly by abstaining from all work in the last few days before an examination, and probably gain considerably in that elusive quality called "freshness."

SUBCONSCIOUS ELABORATION

Mental freshness as opposed to "staleness" is probably dependent on several factors. One of these is "retro-active inhibition"; it has been found by experiment that if two tasks are learned in quick succession the acquisition of the second to some extent impairs the memory of the first. Another factor in "freshness" may depend on this: there is probably involved, in the learning of any task, a process of subconscious elaboration, which occurs more readily in the intervals of freedom from intensive conscious mental work. This subconscious elaboration is evident in dreams. Coleridge is said to have written *Kubla Khan* from the memory of a dream he had while sleeping under the influence of opium. He had been reading a passage about the palace of Kubla Khan from Purchas's *Pilgrimage* just before he fell asleep, and he wrote down all he could remember of his dream immediately on waking. Usually, however, where composition occurs in dreams and seems to the dreamer to be of superior quality, he finds that what seemed so wonderful in the dream is commonplace, or even meaningless, on waking. Graham Wallas, in his book *The Art of Thought*, records that a relative of his woke one morning with the conviction that she had achieved immortality by the lines

'Leave then thy steed
And let it feed
On more than meets the eye'

On subconscious elaboration seems to depend also the not uncommon experience that a problem—say, a geometrical rider—which has puzzled a person for hours of an evening, may very rapidly be solved with but little more effort on waking the next morning. Similarly, some hysterical persons have the reputation of showing much better arithmetical ability in their dissociated state than in their ordinary waking condition. In composing a dissertation on some subject, especially if it is of a theoretical kind, a similar process occurs. One reads up all the relevant literature, which is necessarily come by in a disconnected way, but when one proceeds to write down the impressions gained from it, and to incorporate them in whatever view one has of the subject, the dissertation seems largely to write itself, the views of others fall relevantly into place in a natural fashion, suitable collocations often occurring in a way certainly not realized before the actual writing was begun.

Instances of a more fruitful kind of subconscious elaboration have frequently been related by men of the rank of genius. It was de Maupassant, I think, who said, *Ce n'est pas moi qui pense ce sont mes idées qui pensent pour moi*. Helmholtz, speaking of his methods of thought, said that, after preliminary investigation of a problem, "happy ideas come unexpectedly, without effort, like an inspiration. So far as I am concerned, they have never come to me when my mind was fatigued, or when I was at my working table. They came particularly readily during the slow ascent of wooded hills on a sunny day."

Wallas divides the process of elaboration of new ideas into four phases. The first of these is Preparation, the stage during which the problem was investigated in all directions, the second is the stage, during which Helmholtz was not consciously thinking about the problem which I shall call Incubation, the third, consisting of the appearance of the 'happy idea' together with the psychological events which immediately preceded and accompanied that appearance, I shall call Illumination. The fourth stage is that of Verification, in which "the validity of the idea is tested and the idea itself reduced to exact form."

It is clear that if these methods of geniuses hold also for lesser men, periods of freedom from conscious mental work are more than justified. Psychologists have recently argued against this view, which was dramatically overstated in the pronouncement, "We learn to skate in summer and to swim in winter." But most of us have noticed that our best

ideas, poor things as they may be, often come to us while we are shaving, or in our bath, or engaged on some other desultory activity involving no mental effort. The philosopher Hobbes kept a little notebook where at any hour of the day he would enter the thoughts that "dart" into the mind from the "fringe" of consciousness. Graham Wallas recommends that "anyone who is living a life of intellectual production will do well to keep, as Darwin did, a rather considerable number of 'folders' or envelopes, labelled with the names of subjects to which he finds his mind recurring even although he may not immediately contemplate writing, or lecturing or acting on them." In corollary also the danger from another aspect of too much and too continuous reading has to be remembered: such habits of reading teach us not to think for ourselves but to expect our ideas always to be spoon-fed into us. Independent observation and, wherever it is practicable, experiment to "find out the secrets of nature," are the best correctives.

MEMORY AND ASSOCIATION

To return to nonsense syllables it is dangerous to argue from the learning of these to the learning of sensible material such as comprises any connected body of knowledge. Into the acquisition in memory of the latter much more enters than mere "physiological retentiveness," whereas the learning of the former implies merely the formation of motor habits. A poem or piece of prose is much more completely and easily remembered, as everyone knows, than a series of disconnected words. Nonsense material committed to memory has been found to have disappeared completely at the end of four months, whereas verse will persist for years. An old man, with such senile cortical deterioration as causes him to forget completely what occurs from day to day, will recollect whole series of verses which he committed to memory sixty years before. Frequently one sees advertisements of methods of improving the memory. Even if it be admitted that innate retentiveness, in James's sense, can be increased, which is doubtful, the principal improvement in memory must depend on the multiplication of associations, and most of the advertised tonics for invigorating a feeble memory utilize this fact. Ingenious methods, such as the formation of mnemonics or the invention of 'figure alphabets,' in which each numerical digit corresponds to a letter, are typical of the schemes recommended. James mentions a system advocated by E. Peck in 1833, which consisted in linking together any two ideas by means of an intermediate idea. Such 'ingenious methods' occupy more time than they are usually worth.

The number of associations that a new body of information forms for itself depends upon the number and kind of previous acquisitions. One of the most important—probably the most important—factor in a good memory, especially in the sense of a serviceable memory (and not of mere mechanical registration and reproduction) is the multiplication and verification of the connexions of our experience. To take a very simple example in preparing for an important examination it is unwise to use only one textbook. Some textbook or other should be made the mainstay, but reference to another, even by borrowing it from time to time, will present new viewpoints, or at least will present things in a somewhat different order, in such a way that new associations will be formed for the material gleaned from the staple volume. Still more important is it to talk about the subject in as many of its bearings as one's fellow students can be prevailed upon to discuss (which may not be many). "If a man confer little," says Bacon, "he had need have a present wit." Attendance at lectures has a similar justification. If the lectures are expositions of a subject, and not mere essays read aloud in public, they stimulate associations in the same way. In these days of cheap and well made books this is one of the few remaining justifications for the survival of systematic lectures.

In merely learning anything by heart certain devices are of value. The grouping of the material to be learned into intelligible unities naturally occurs to everyone. The presence of rhythm makes learning easier, for example, poetry is easier to learn by heart than prose. This is presumably related to the fact that every mental and bodily activity tends to be rhythmical. It has also been

found experimentally that if a poem of several verses has to be memorized, it is more economical and effective in the long run to learn it as a whole, rather than stanza by stanza.

Interest is naturally also of vast importance. We remember best what interests us most, although the retention of what has not appeared to interest us at the time, but has remained in the "marginal field," is sometimes remarkable, as we have seen. Interest reduces, also, the effort both of attention and remembering, and it increases the powers of observation as well. It is a frequent occurrence that when a name or a word which we do not seem to have encountered before comes to our notice, and which interests us by its very unfamiliarity, it crops up repeatedly in our experience in the next few weeks. On a similar focusing of interest depends the common "fallacy of the positive instance." Interest leads also to selection. Under the influence of interest we select—often without realizing it—what we wish to remember. But everything should not be left to this more or less instinctive selection. There is with some people too much slavish routine reading, too much of ploughing through masses of more or less unnecessary and irrelevant texts, omitting nothing, lest anything be missed, as some people read every page even of the inferior works of fiction produced by a good author. "Some books are to be read only in parts, others to be read, but not curiously, and some few to be read wholly, and with diligence and attention." Closely related to interest and attention is the general attitude of the student. Too many men sit down to a book or a problem without troubling to form a general notion of what they expect to get out of it.

It has been held by some that every experience is retained—everything seen or heard or done in our life up to date—that nothing is ever completely forgotten. There is no evidence for this statement, and it would be very awkward if it were true. "A good memory for forgetting" sounds like a contradiction in terms, but consider what would happen if we did not, for all practical purposes at least, forget much of our experience. Otherwise, in recalling some event we would laboriously resuscitate every smallest detail that had ever happened contemporaneously with it, and its recollection would occupy nearly as much time, perhaps, as the event itself. In this way we would never be done and could hardly have time available for registering new impressions from the intruding complex burden of the old. How much, for example, of the events of our earlier years do we seem to remember? The first ten years of our lives we could perhaps dismiss in as many minutes, having recollected all we can of them. Nevertheless, although our memory is not of everything we ever experienced, modern psychopathological research has shown it to be much greater than was formerly suspected.

Memory then, so far from being all-inclusive, is selective. The best memory is possessed, as we have said, by the man who makes the greatest number of associations with his experience, but the most effective memory is a combination of associative richness with selection. The organization of memory in accordance with one's prevailing interests is the most effective organization. The man who thinks about his experience has much the better memory. This, by the way, marks the point of distinction between crammed information and real knowledge of a subject. In cramming one does not think—few associations are formed, real knowledge involves organized associations formed under the influence of continued interest.

Much better than a slavish devotion to the minutiae of one subject, is a study, less minute, but more comprehensive, of several. It has frequently happened that outstanding contributions to one science have been made by men trained in some other, they have, in consequence, approached problems from a new and fruitful aspect. For example, physicists have contributed much to astronomy, chemists to physiology, and mathematicians to everything. It is interesting to find how many of the men who have done exceptional work in one branch of medical science have begun their medical work in some other, often only distantly related. The absence of a narrow specialism has been until recently (and still is, to some extent), one of

the glories of medicine in this country. "For expert men can execute, and perhaps judge of particulars, one by one, but the general councils, and the plots and marshalling of affairs, come best from those that are learned in many fields." Fertility of invention arises largely from the interplay of associations, diversity of interests (provided that intensity of interest does not suffer) facilitates such interplay.

HABITS OF WORK

Associations can be multiplied not only between cognate fields of knowledge, but within each field itself. Some of these methods have been mentioned above, for example, by discussion and debate, and by reading different books in the same field. There is another method, which is among the most efficacious, and that is, to write about the subject. To quote again the inexhaustible Bacon, "Reading maketh a full man, conference a ready man, and writing an exact man. And, therefore, if a man write little, he had need have a great memory." It is not, however, merely that writing about a subject improves the memory of it, still more it improves the clearness of a subject in the mind. Writers of monographs and textbooks not infrequently acknowledge that the persons to whom the writing has been most beneficial are the authors themselves. Lord Kelvin is reported to have said that he did not feel that he fully understood anything until he had made a working model of it. Most of us cannot, without disproportionate labour, make a working model of a problem in carbohydrate metabolism, or even of a murmuring heart, but to be able to write a coherent and lucid description of such things is a great advance on merely having memorized some textbook account of them. It is not possible to perform this service for every topic while preparing for an examination, but how seldom is it done even for the most difficult. One of the most valuable of such exercises is the writing of "papers," especially papers on some piece of "original" work (it need not be very original), and not merely critical summaries of literature. The latter, however, can also be very useful in this way, for the reading of original articles in the medical press and the constructive summarizing thereafter of a number of articles on kindred topics is a pleasant and often very stimulating variant to poring over textbooks. It also has the advantage of "mobilizing" one's knowledge. Original work, being less cut and dried and dogmatic than textbooks leads to questioning and to an open mind. The air of authority, too, is less overwhelming in them than in standard books, the constant perusal of which, if unvaried by occasional resort to originals, tends to stifle intelligence. The first few years after graduation have often to be spent by the young medical man in ridding himself of the unquestioning faith in authority and the printed word that he has acquired during his student days, and of the parrot-like habits of memorizing, rather than understanding, a subject which, in defiance of the methods recommended above, many men adopt in their work for examinations. It is a good thing that the student should regularly read—in selective fashion, of course—one of the current general medical periodicals, together with occasional numbers of the more specialized journals, dealing with any subject to which he happens to be specially attracted.

Finally, method, in the sense of orderliness, is a great asset, not only in the acquirement of learning, but in its serviceableness afterwards, and so long as it does not become a fetish, it betokens an orderly mind. The methods adopted must vary with the individual, and with the nature of subject which he is endeavouring to master. Some lay stress on regularity of working habits, it is a good thing, for example, to have a prescribed routine of beginning work at certain hours and working for a certain period of time. A habit can be thereby established which, like every habit, has a certain dynamic effect of its own. Moreover, habit facilitates the "slow dead heave of the will" that overcomes the inertia existing in the most willing people at the beginning of any task, and which is probably a property of mind itself, and even that other inertia which is present in the rest of us, and is a thing of the spirit.

I have to thank Dr. Shepherd Dawson, Dr. C. P. Blacker, and Professor T. B. Johnston for valuable suggestions.

The Profession of Medicine.

INTRODUCTORY

THE profession of medicine, like every other, has its advantages and its drawbacks, and all who think of entering it should try to weigh the one against the other. Our main object throughout this Educational Number of the *British Medical Journal* is to be of assistance to prospective students and their parents, and to those who have lately joined our ranks. Thus, while the pages that follow give full information about the steps that must be taken and the studies that must be pursued in order to become a registered medical practitioner, the Educational Number as a whole is much more than a mere abstract of prospectuses and regulations. It is intended to serve as a kind of guidebook both for those wishing to know what a medical career has to offer, and for others who, having obtained a legal qualification to practise, are uncertain about the line of work for which they are best suited. As in past years, this introductory article gives an opportunity to review some aspects of medical study and practice to-day, in order to put the situation as we see it before those who think of devoting themselves to medicine, and thus help them to gauge their fitness for the calling and the prospects it holds out.

The intending student will find in subsequent pages an account of the course of training required of him, the places where it can be obtained, and the universities and other licensing bodies which test the knowledge gained and confer degrees or diplomas certifying successful candidates to become legally qualified medical practitioners. Sections are included also on post-graduate medical study, on the higher qualifications, both general and special, and on the many and varied spheres of medical work open to registered medical men and women at home and abroad. The details given are founded for the most part on official information, and are arranged along the customary lines.

THE GROUNDWORK OF MEDICAL STUDY

"The most important thing in the education of a really good doctor is his general education." This is the plain truth, spoken the other day to an American audience by an authority on medical education in this country. Next in importance is a good scientific education—a thorough grounding in the basic principles of science. Upon these the student of ordinary intelligence and industry can build up an adequate technical equipment for the practice of his profession. Medicine is an art founded on science; hence the need for a real training in science and the scientific spirit. The temptation to take short views and shortcuts is very strong in the early years of the medical curriculum, but a greater mistake cannot be made than to work at any branch of preliminary study as though it were something to be thrown aside and forgotten when the examination immediately ahead has been passed. The student who has had a good general education and who uses this to master the essentials of each of the fundamental subjects need have little dread of examiners. Moreover, these sciences give a drilling in exact methods in precise manipulations, and in vigorous reasoning which will bear immediate fruit in the clinical part of the curriculum and prove of lasting benefit throughout professional life.

The purpose of a sound training in medicine is to raise on scientific principles a solid structure of practical knowledge and practical skill. Students who keep this in

mind will look upon "exam work" as a weakness in the foundations, and therefore as a hidden danger to the superstructure. Chemistry, physics, and elementary biology prepare the way for anatomy and physiology, and so for medicine and surgery and obstetrics. All authorities are agreed that these preliminary and intermediate sciences form the only appropriate introduction to the study of medicine. It has been well said of the great John Hunter that he "studied anatomy and physiology to get help in diagnosing and treating his patients. He studied dead things to understand the living, and observed living things to understand the dead. A knowledge of how this body is made and how it works must provide the basis for all the more practical subjects of medicine." So much for the groundwork.

PORTALS OF THE PROFESSION

The obvious goal of every student is the entry of his name in the *Medical Register*, which is the official statutory list of qualified medical practitioners kept by the General Medical Council. Those who are not acquainted with the system of medical teaching and examination in these islands, and with the history of our professional institutions, may well feel bewildered at the number and variety of ways in which admission can be obtained to the *Register*. They will see in the table of contents to this Educational Number that there are no fewer than twenty-seven bodies—eighteen universities and nine corporations—which either separately or jointly issue registrable qualifications, and the number of teaching institutions is even larger. Nevertheless, although we have no single State examination in medicine—no "one portal" as it has been termed—the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines and the obligatory curriculum is much the same for all students. As, however, the individual teaching and examining bodies have different standards and requirements, the choice should be made early, so that a definite plan may be followed. A candidate may, through ignorance, either choose a portal beset with so many difficulties that time and energy which might more profitably be used in some other direction are wasted in efforts foredoomed to failure; or, on the other hand, he may choose one which too late he finds does not open the way to a career suited to his taste and ability. It is therefore important to gain some idea of the value, in different walks of medical life, of the various degrees and diplomas, and of the comparative difficulties they present.

All who wish to enter the profession must comply with certain conditions. These are regulated by the General Medical Council which is a statutory body set up under the Medical Acts, a summary of its functions and requirements is given at page 375. Many changes have lately been made in the medical and pre-medical curriculum, and this section, as well as the article on Professional Study and Examination should be studied with care. It is the business of the General Medical Council so far as possible, to see that a suitable kind of training and the requisite degree of knowledge are secured to the student, and it is the business of the medical schools and examining bodies to give the training and test the knowledge in accordance with the requirements of that Council. Every student, after passing examinations in the subjects of general education and in the preliminary sciences of chemistry and physics, must take a course of training at a recognized

* Sir Norman Walker. Medical Education in Great Britain and Ireland. *Journ. Amer. Med. Assoc.* April 14th 1928 p 1181.

* Sir Arthur Keith. *British Medical Journal* September 4th, 1926 p 410.

medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession, is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees, in the case of a university, or diplomas or licences, in the case of a corporation, these qualifications entitle them to claim insertion of their names in the *Medical Register*. Every student, as soon as he obtains his qualification to practise, should at once register, otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied, and so many practitioners are now graduates in medicine that a student at the threshold of his career will do well to consider the advantages of possessing a degree, though it may be desirable to take also a diploma or licence. The medical degrees (M.B., M.D., etc.) granted by the universities in Great Britain and Ireland are mentioned among the particulars about each university printed in later sections.

COST OF MEDICAL EDUCATION

For the ordinary student the cost of medical education resolves itself into the cost of the training at medical school and hospital, and the cost of living during the five or six years of the curriculum. The expenses under these two main headings vary considerably. Besides differences in the charges made for instruction, there are differences in examination fees, as well as in the fees for certificates of qualification, and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students, however industrious, have the knack of imparting what they know to an examiner, and every setback due to failure in the examination room or to illness means added expense. School and examination fees, together with the cost of board, lodging, clothes, and recreation, form the largest items of expenditure, and to these must be added the money spent on books, microscope, instruments, and so forth. Since professional education must in any case continue for five years at least (a period exceeded by the vast majority), and since the cost of living in different parts of the country varies much, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should be prepared for an outlay of at least £1,500. Something between two-thirds and three-quarters of the whole amount would probably be spent on maintenance, and the rest in fees, etc., for tuition and examination. The composition fees charged by the different medical schools are stated in the paragraphs relating to each on other pages of this issue. In making any kind of 'trial estimate' the manifold helps available nowadays for the reduction of expense should not be ignored. At nearly all the medical schools more scholarships and money prizes are offered now than in the past, at the Scottish universities bursaries are numerous, and the Carnegie Trust (whose regulations are summarized at page 387) gives pecuniary help to many Scottish students. The main thing to bear in mind is that,

as compared with other professions, the period of training in medicine is long, and for most students expensive. Further guidance on this matter will be found in a memorandum,¹ drawn up by the Registrar of the General Medical Council, on the procedure to be followed in order to enter the profession. This pamphlet gives much useful information, including a comparative table of the cost of study and examination at the various institutions.

Medical students are not commonly the sons or daughters of wealthy parents, very often their education puts a heavy strain on a slender family purse. Hence, before setting out upon this long and exacting course of study, it is usual to weigh, not only the cost, but also the prospects. An overcrowded curriculum would be hard to face if all that could be discerned at the end of it were an overcrowded profession. Without forgetting the adage "there is always room at the top," the youth and the girl of to-day, when reckoning up their chances in any calling, will wish to know the probable numbers of their competitors for the work that is waiting to be done.

THE NUMBERS OF MEDICAL STUDENTS

The following brief survey of the numbers of new medical students in recent years should be read with the notes and tables printed at page 374 on the numbers of registered practitioners. More new students mean more new doctors five or six years later, though, as the chart shows, there is in normal times a fairly constant wastage, due to one cause or another.

For the last thirteen years of the nineteenth century the average entry of medical students in Great Britain and Ireland had been about 1,800, but for the next thirteen years the average was about 1,400. During the war period, although many left to serve with the forces, the whole number studying in the schools grew steadily larger. Thus in 1914 the entries rose to 1,600, and in 1915 to 1,918, in 1916 they were 1,875, in 1917 they rose again to 2,150, and in 1918 they were 2,253, while in the following year, when demobilization was in active progress, as many as 3,420 new students were registered. After 1919 the number of entries rapidly fell. They were 2,531 in 1920, 1,808 in 1921, and 1,833 in 1922. In 1923 they dropped suddenly to 545. This abrupt falling off was, however, more apparent than real, the reason being the introduction in that year, under the new regulations, of a pre-registration test in elementary physics and chemistry. In 1924 the students' entries were 1,043, in 1925 they were 1,070, in 1926 they rose to 1,260, and last year they were 1,214.

The recent decline is an advantage, because the excessive entries of students during the post-war inflation period, if they had gone on long enough, must have led to overstocking of the profession. In the past six years the numbers of new practitioners have greatly exceeded the usual pre-war figure of eleven hundred or so. Registrations in 1922 numbered 1,983, they rose to 2,482 in 1923, and to 2,796 in 1924, in 1925 they were 2,570, in 1926 2,120, and last year 1,941. The large additions to the profession in recent years brought the total number of names in the *Medical Register* up to 53,769 at the end of 1927. This is nearly ten thousand more than the figure for 1917, and fourteen thousand more than that for 1907. There has been no corresponding increase of population in the British Isles during the same decennial periods, and the ratio of doctors to inhabitants is therefore much higher now than ever before. It is true that the scope of medical practice has widened considerably in the meanwhile, and many fresh openings for professional work have followed the growth of diagnostic, curative, and preventive methods, and the rapid development of administrative medicine.

¹ Memorandum on the Procedure to be Adopted by those who intend to enter the Profession of Medicine, with Notes on Costs and Prospects, 1927. General Medical Council, 43, Abchurch Lane, Portland Place, W.1. Price 1. post free.

But there must be bounds to the legitimate medical needs of the community. The new regulations of the General Medical Council, though they were drawn up for another purpose, have tended so far to keep the entries of students within manageable limits and so to maintain a balance between supply and demand.

On the whole, it may be said that for those of good average intelligence and physique who are not afraid of work, the prospect in medicine to-day is quite favourable. The medical profession of this country is not overstocked. Its numbers are still badly distributed, though perhaps not quite so much so as at the beginning of the century.

ATTEST REGISTRATION CHOICE OF A CAREER

The student, having passed all his tests and placed his name on the *Medical Register*, becomes a member of the profession and assumes the privileges and responsibilities that go with legal qualification. But after a qualification to practise has been obtained there is usually a period of transition from the stage of the medical student to that of the established medical practitioner. This time may be put to the greatest advantage by serving as house-physician, house-surgeon, or casualty officer in a hospital by working as assistant or locum-tenent in private practice or by seeing something of the world as a ship surgeon. As a preliminary to practice of whatever kind, nothing is so useful as a year or more spent in junior hospital appointments and all who can afford the time should look upon the holding of such posts as a most profitable investment.

If his mind is not made up already, the young practitioner has now to consider in which branch of the profession he can put his abilities to the best use. The choice is very wide. Among the great variety of paths open to those with different tastes and talents are general practice in town or country, Government service at home or abroad including, of course the medical branches of the Navy and Army and Air Force, and the I.M.S. public health appointments and other administrative or official posts, institutional work, such as that of the mental hospital and Poor Law medical services, and special work in scientific research and teaching, or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in the later sections of this Educational Number, but a few words may be said here about general practice and the work of a consultant or specialist.

Further information and advice on such matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.¹ This comprises articles on the main openings for members of the profession, on some practical aspects of medical work, especially the legal and ethical aspects, on registration and the privileges of practitioners, on medical practice under the National Insurance Acts, on post-graduation study and special diplomas on specialization and consulting practice, on the fellowships, scholarships, studentships, prizes, and research grants open to students and practitioners, and on societies undertaking individual medical defence. The section dealing with practical aspects of professional work will be found of much value to all medical men and women. It embodies a great deal of advice on professional conduct in general, on medico-legal difficulties of common occurrence, and on the relations between doctor and patient and one doctor and another.

GENERAL PRACTICE

General medical practice has hitherto been, and still is, the destination of the great bulk of students. It is estimated that three-quarters at least of those who pass out

of the medical schools become "family doctors" sooner or later. The work is onerous and the pay too often inadequate, but there are compensations, for it is a full life rich in human interest, and many of the very best students now as formerly, choose general practice as a career. Their work is of the utmost value to the public and the profession, because it sets a standard for the branch of medicine in which the generality of students sooner or later become absorbed.

This field of professional life is usually entered in one of three ways. The newcomer may take a house, put up a plate, and wait for work to come to him, he may buy the goodwill of a practice rendered vacant by retirement or death, or he may become a partner in an established firm. The first is more risky than the second, and the second than the third. A well managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy. A good many general practitioners therefore begin their work as assistants, and of these few find cause to regret the time spent in learning the ropes under the eye of an experienced senior. As the circumstances of general practice vary much from place to place it is usually best to serve this "post-graduate apprenticeship" under conditions resembling those to be met later. An all round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some special branch of work, and the experience gained when holding clinical assistantships or resident posts (not necessarily in teaching hospitals) will prove invaluable in general practice.

The fundamental value of the work done by the general practitioner is better appreciated now than in the past and it is more fully recognized that an efficient medical service must be based upon the skill and devotion of the family medical attendant, working in close touch with the aims and methods of preventive medicine. Under the conditions of to-day his place in the community is more important than ever before. Private practitioners now take a wider view of their duty towards the environment and the habits of their patients than in former times, when they were almost wholly concerned with developed disease in individuals. The doctor of the future will come more and more to study early disturbances of function—the threshold of disease—and the maintenance of bodily and mental health in varying conditions of life and work. While this is all to the good, it cannot be denied that encroachments on private medical practice are perpetually being made, here a little and there a little under the auspices of the State and of voluntary bodies. If such inroads threatened only the material interests of the individual doctor they might have to be endured, like much else that goes on in the name of progress, but it is not difficult to show that in the long run many of them must react against the public interest also. Another trial for the private medical practitioner arises from the multiplication of official requirements and administrative checks imposed by public authorities. Apart from the clerical drudgery thus put upon him, these new demands must tend to cramp the doctor's independence of judgement and action and to divert his mind from purely medical duties.

The national system of compulsory health insurance, now more than sixteen years old, has inevitably had a profound influence upon the great bulk of private practitioners in

¹ *Handbook for Recently Qualified Medical Practitioners*. British Medical Association, Tavistock Square, W.C.1. (3s. 6d. net post free 3s. 9d.)

² A book of practical advice for the newly qualified entitled *How to Start in General Practice* by Isaac C. Briggs is published by John Murray, price 6s.

this country, so much so that it is already difficult to call up a clear picture of what medical practice was like in working-class districts less than a generation ago. The Insurance Acts provide domiciliary medical attendance for some sixteen million persons, and nearly 15,000 members of our profession now undertake responsibility for the medical care of this vast section of the population. These practitioners, by placing their names on the panel (or medical list) signify their assent to the terms of service set out in the Medical Benefit Regulations and other relevant provisions. It would have been strange indeed if a measure so far-reaching and so complex had not brought about great changes in the conditions of general practice, with some detriment to the freedom of the individual doctor. On the other hand, there is general agreement that the panel system has provided a better service than existed under the old "club" arrangements, though it is by no means as complete or as effective as it might be made. Some of its worst faults have been removed through the efforts of the Insurance Acts Committee of the British Medical Association, which represents the interests of the insurance practitioners in all negotiations with the Ministry of Health. "Under the Act as it stands much more could have been done, and should be done, in the matter of wise propaganda directed to the means of preserving health and of preventing disease, but, taking the Act in general, with its many inherent administrative difficulties, it can be said that the major provisions are being sympathetically and effectively implemented. But the degree of success so far attained in itself calls for further and fuller developments, which in due course should be equally available for all insured persons regardless of their membership of any particular society."¹

CONSULTANT AND SPECIALIST PRACTICE

The term consulting practice may be said to comprise in ordinary usage the work of the general medical consultant or "pure physician" and that of the general surgical consultant or operating surgeon. Most general consultants, whether medical or surgical, are specialists in some branch of their practice, and most specialists are consultants in the sense that their work largely comes to them through the recommendation of other practitioners, with whom they act (or should act) in a consultative capacity. In any case, whoever holds himself out as one or the other or both must be assumed to have knowledge and skill above the ordinary.

To be a competent specialist a man should possess, as a background to his expert attainments, a comprehensive knowledge both of medicine and surgery, and if possible should have practised for some years before starting on his own line of work. Intensive study is required of those who aim at becoming consultants or specialists, and they should look upon hospital posts, especially where there are students to be taught, as a vital part of their higher education. For them, as for practitioners of all branches, success will depend in the long run, not only upon mental gifts, special experience, and capacity for hard work, but on the possession of those qualities which inspire confidence both in patients and in colleagues. Moreover, since the consultant or the specialist can scarcely hope at first to pay his way by consulting work or by the exercise of his specialty, he must either have private means, or be prepared, by teaching or in other ways, to make ends meet. If while in preparation for his life-work he can undertake some piece of research bearing upon his clinical studies, this is most advisable, and there is much to be said for spending some months in visits to foreign clinics.

Additional degrees and diplomas are important factors in securing election to the visiting staff of a large hospital, and a few remarks about them may be made here. Beyond the qualifications, such as Bachelor or Licentiate, which admit to the *Medical Register*, most of the licensing bodies bestow higher titles, such as Doctor, Master, or Fellow, after further tests. A considerable number of those who have graduated M.B., including many general practitioners, proceed later to the doctorate, and the possession of an M.D. degree is certainly advantageous to anyone in consulting medical practice. When applying for the post of physician to a hospital it is always useful, and may be obligatory, to hold also the Membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which the hospital is situated. So, too, the Fellowship of one of the three Royal Colleges of Surgeons should be obtained by those seeking surgical appointments, and the degree of Master of Surgery is an added distinction. There are also diplomas in a growing number of special branches of work—such as public health, tropical medicine, ophthalmology, laryngology, radiology, tuberculosis, and psychological medicine—which are superfluous for most practitioners, but useful or even indispensable for those who intend to devote themselves to one or other of these subjects. Information about the several diplomas open to qualified practitioners, and about higher degrees, will be found in other parts of this issue. It should perhaps be noted here that of the many diplomas in special subjects granted by licensing bodies only those in public health, sanitary science, and State medicine are at present admissible for entry in the official *Medical Register*, though other special diplomas may of course be included among the particulars of qualification in the *Medical Directory*, published by Messrs J and A Churchill.

A comparatively new feature of medical life, more especially seen in the larger industrial towns of the North of England, is the presence of a growing number of general practitioner specialists, who combine ordinary panel practice with much surgical or other special work in well equipped local hospitals which admit patients in different categories according to their means. Though the fees are small compared with those earned by operating surgeons and specialists in London, the work is by no means unremunerative, and it adds a great deal to the interest of the daily round.

FINANCIAL AND SOCIAL ASPECTS

The pecuniary disadvantages of medicine as a profession are the long and costly training, the time of waiting after qualification before the practitioner can count upon an adequate income, and the heavy working expenses in proportion to his gross earnings. On the other hand, the medical profession affords a fairly certain means of livelihood, with unrivalled opportunities for the exercise of the highest intellectual powers in the service of others. The counterpart of the briefless barrister is practically unknown in medicine. But while no doctor who is willing and able to work need starve, it should be clearly grasped by all who think of adopting it as a career that medicine is a path to fortune only for the few, and anyone who enters it with the sole idea of making money has mistaken his calling. The distinguishing feature of a liberal profession in contrast with a trade is that it is followed more for the general good than for individual profit, the main reward of the medical life is the knowledge of good work well done. Whatever the branch of medical work chosen, there are few doctors who become what a business man would consider even moderately rich by the practice of their profession. Yet, if medicine, from the financial point of view, offers to the majority little more than the means of livelihood, in its social and intellectual aspects the prospect

¹ Sir Ewen Maclean, Presidential Address to the British Medical Association, Cardiff July 1922.

is far brighter. The practitioner's lot is unlike that of many whose common business gives little scope to the higher faculties of the mind, for it is his duty and his privilege to live in, and by, the constant exercise of his intellectual powers. Moreover, the culture which once belonged to the physician alone has spread into all ranks of the profession. The steady improvement in the education, general as well as technical, of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the seventy years that have passed since the General Medical Council was constituted under the first Medical Act. A family doctor of the kind that is well styled "the backbone of the profession" holds an excellent position among his neighbours, and is the friend and confidant as well as the medical adviser of many of his patients. Many men go further, and take a leading part in the public life of their district. There are conspicuous instances within our knowledge of the good work in this direction that has been accomplished during an arduous professional career. A proof of the special value of a medical training is the way in which it fits men for leadership among their fellows.

PROFESSIONAL ORGANIZATION

It is a sound rule of conduct that the new practitioner should associate himself as cordially as possible with neighbouring colleagues. The spirit of comradeship, which contributes so much to the value and happiness of undergraduate study, should be preserved, both for its own sake and because in these days no doctor, whatever his position or the nature of his work, can safely stand aside from his fellows. Individuals and isolated groups of practitioners are always handicapped when they attempt to defend their interests against organized bodies, whether these are Government departments, local authorities, or bodies of workmen. In the ordinary course of work the individual doctor is well able to deal with the individual patient and the patient's friends, but he cannot hope to engage successfully in single combat with outside organizations. Apart, however, from such motives of self-interest, every one of us owes a duty to his profession, and the man who holds himself aloof from his brethren fails in that duty and by so much lessens the power and dignity of medicine. Medical men and women must therefore band themselves together, and the first step after registration should be to become an active member of the British Medical Association. Besides having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division, and in the Annual Meetings of the Association, held in large medical centres, many opportunities for keeping abreast of new work in medicine and for friendly intercourse with colleagues. One other thing that no new graduate should fail to do is to join immediately one of the professional societies which for a small yearly sum undertake individual legal defence of their members. It is sheer folly to put this off even for a day. The need for protection may arise out of the first case attended in hospital or in private practice.

The British Medical Association was founded in 1832 to promote the medical sciences and to maintain the honour and interests of the profession, a brief note on its constitution and activities will be found on page 428. The Association, with Branches throughout the British Empire and a membership of more than 34,000, is the only body that can act for the profession as a whole and speak in its name. The record of ninety-six years' work shows that vocational organization, wisely directed, can combine service for its members with service for the public. Much remains to be done in both ways, and those who are now entering

the profession must not merely consolidate the ground won, but press forward. Every medical man and woman should try to take a share in some at least of the various movements, scientific or social or political, with which the Association has identified itself.

PROFESSIONAL STUDY AND EXAMINATION

THE REVISED SCHEME OF 1922

In 1922 the General Medical Council prescribed a readjustment of the medical curriculum, to come into force at the beginning of the following year. The scheme adopted was in effect a compromise between several "schools of thought" which had been debating the matter for fifteen years or more. In this readjustment among other things, increased emphasis was placed upon sufficient opportunity being afforded for the study, both theoretical and clinical of those subjects which are now so essential in connexion with the treatment centres of a local authority, such as ophthalmology, venereal diseases, orthopaedics ante natal conditions, and infant welfare. Our article printed in page 386 last year on the functions and requirements of the General Medical Council includes the text of the resolutions and recommendations of the Council which have applied since the beginning of 1923. We summarize below the leading features of the revised scheme of professional study and examination, and indicate the importance attached by the Council to the preventive aspects of medicine. The first qualifying examinations based upon this readjusted curriculum have been held during the present year.

THE MEDICAL CURRICULUM TO DAY

The minimum age for registration as a medical student is now 17 years. There has been no formal lengthening of the medical curriculum under the revised scheme, but in practice it has been added to by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. Thus in addition to passing a preliminary examination in general education, an examination (written, oral, and practical) in the elements of physics and chemistry is required by the General Medical Council before the admission of a name to the Students' Register. In the applications of these two subjects to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum and is to be tested by examination so that the student shall no longer be able to put behind him as past and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary or pre-registration examination in chemistry and physics, then he can come for it to the university or medical school, but study there will not count for the medical curriculum. In elementary biology comparatively few secondary schools are equipped for tuition but the General Medical Council has suggested an arrangement for utilizing the work of such schools as are qualified for the purpose. The examination in elementary biology will not be "pre-curriculum," but the instruction may be so and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, it is the wish of the Council that the applications of biology to medicine, surgery and midwifery shall continue to receive adequate attention throughout the courses.

As Sir Norman Walker said in an address to the Annual Congress on Medical Education, Medical Licensing and Hospitals held at Chicago last February: "This pre-registration examination [in elementary physics and chemistry] is still in the experimental stage and some of the bodies are not very sympathetic to it. Most of them, however, have accepted it *pro tanto*, and we are trying to work this new scheme which has at least this merit—that we can now assume that every student starts the five years' curriculum with a working acquaintance with

the elements of chemistry and physics. The Council has to keep a watchful eye lest the examination should be regarded as a sufficient test of knowledge, and the medical curriculum proper recommended by the Education Committee contains the subjects of chemistry, physics, and biology in their application to medicine."

A Block System

Besides the resolutions of the General Medical Council in regard to professional education and examination printed elsewhere at page 377 a series of additional resolutions was adopted in 1922, as follows

(a) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine,

(b) That each Licensing Body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum,

(c) That the teaching of anatomy and physiology should include as a regular part of the courses the demonstration on the living human body of structure and function,

(d) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology held at the close of the second year,

(e) That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical application to Medicine, Surgery, and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination,

(f) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs,

(g) That instruction should be given, in the courses of Forensic Medicine and Public Health or otherwise on the duties which devolve upon practitioners in their relation to the State and on the generally recognized rules of medical ethics. Attention should be called to all Notices on these subjects issued by the General Medical Council.

The Council, it will be noted, attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the examinations in these subjects have been passed.

Examination Reform

Another notable feature is that in assessing marks in the several examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it, counts far too much in the examination room. The difficulty is real, but the remedy is not easy, and the Council has been wise in the cautious approach it makes towards a solution. Where, as in the examinations for the various conjoint diplomas, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records will be necessary. On the other hand, at the universities, where the teacher is almost always one of the examiners, an personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should, of course, be available, but the scheme will put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest.

Training in Preventive Medicine

The first of the resolutions quoted above should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. All the earlier subjects—physics, chemistry, biology, physiology, anatomy,

and, of course, pathology, bacteriology, and therapeutics also—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view, in all the advice and treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease.

THE NUMBERS OF THE MEDICAL PROFESSION.

A REVIEW OF FIFTY YEARS

During the past fifty-two years the General Medical Council has kept an analytical record of the number of names entered in, added to, or removed from the *Medical Register* in each twelve months. The *Medical Register* has been published annually since the Council was constituted under the first Medical Act of 1858, but before 1876 no such data as these were ascertained.

In order to present a general view of the numerical strength of the medical profession during the past half-century we have extracted from the records and set down below in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the numbers added annually by registration between 1878 and 1927.

Numerical State of the 'Medical Register'

Year	Names added in Year	Total No. on Dec. 31.	Year	Names added in Year	Total No. on Dec. 31.
1878	996	22,600	1903	1,233	37,878
1879	996	22,516	1904	1,168	38,492
1880	1,123	22,836	1905	1,240	39,060
1881	1,063	23,275	1906	1,197	39,529
1882	1,171	23,801	1907	1,221	39,827
1883	1,304	24,517	1908	1,137	40,257
1884	1,398	25,321	1909	1,143	39,813
1885	1,377	25,998	1910	1,062	40,483
1886	1,431	26,452	1911	1,042	40,913
1887	1,531	27,246	1912	1,157	41,439
1888	1,184	27,939	1913	1,168	41,940
1889	1,305	28,348	1914	1,433	42,378
1890	1,266	29,163	1915	1,526	43,225
1891	1,345	29,555	1916	1,202	43,481
1892	1,513	30,590	1917	1,134	43,819
1893	1,573	31,644	1918	1,077	43,826
1894	1,426	32,637	1919	1,322	44,510
1895	1,446	33,601	1920	1,457	44,761
1896	1,385	34,478	1921	1,760	45,408
1897	1,230	34,642	1922	1,983	46,476
1898	1,210	35,057	1923	2,482	48,140
1899	1,351	35,836	1924	2,796	50,035
1900	1,345	36,355	1925	2,570	51,738
1901	1,318	36,912	1926	2,120	52,614
1902	1,275	37,232	1927	1,841	53,769

The varying proportion of registered medical practitioners to population during the period under review is shown in the following table. This sets out the total population of the British Isles at each decennial census since 1881, and the number of names on the *Medical Register* in the same year, also the corresponding totals in 1926, that for the general population being an official estimate.

Proportion of Practitioners to Population

Year	Registered Practitioners.	Population, British Isles.
1881	23,275	35,241,482
1891	29,555	38,104,975
1901	36,912	41,976,827
1911	40,913	45,370,530
1921	45,408	47,146,506
1926	52,614	48,190,000

These figures show a steady increase in the ratio of doctors to population, which was accelerated during the years immediately following the war. The number of registered practitioners at the end of 1921 was almost exactly double the number at the end of 1876, but the population of Great Britain and Ireland within that period only increased by about 50 per cent. During the year 1927

the new medical registrations numbered 1,941, and there was a net increase of 1,155 names. There is now considerably more than one name in the *Medical Register* to every thousand of population. In the United States of America it is estimated that there is at the present time one medical practitioner to every 753 people. Next to the United States the British Isles appear to have the highest proportion of practitioners to population. Switzerland has approximately one doctor to every 1,135 inhabitants, Germany 1 to 1,320 and Denmark 1 to 1,200.

REGISTRATION OF STUDENTS AND PRACTITIONERS

The relation between the numbers of new students and those of newly qualified practitioners during the past twenty years is shown in the accompanying chart, reproduced from the last report of the Finance Committee of the General Medical Council.

The figures for the registration of practitioners year by year apply only to those whose names were entered on the

British list, entries in the colonial and foreign lists of the *Medical Register* being excluded, hence the slight discrepancy between the totals indicated in this chart and

those given in our tables printed above. The chart brings out in a striking way the difference between the number of registered students who should have completed a six years' curriculum in a given year and the number of newly qualified practitioners who in fact registered in that year. In 1919, following the armistice, there was an enormous entry of students, but, as was only natural in the circumstances, a considerable proportion dropped out of the running year by year, and in 1925 the number of those who qualified fell short of expectations by nearly 1,000. Since then the two

Numbers of medical students and practitioners 1908 to 1927

figures have approached each other again, and it is reasonable to suppose that the pre-war relationship between them will be resumed. Some further remarks on the numbers of medical students in recent years will be found in our introductory article on the profession of medicine.

THE GENERAL MEDICAL COUNCIL

THE General Medical Council was established by the Medical Act, 1858, in order 'that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners.' It consists of eighteen members appointed by the Universities in the United Kingdom having medical faculties, of nine members appointed by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons, of five members appointed by His Majesty in Council and of six members directly elected by members of the profession as a whole—a total of thirty-eight. To these are added three dentists who are members of the Dental Board and are appointed for dental business. Although the eighteen members appointed by the Universities and the five members appointed by His Majesty in Council may all be laymen, only one layman has so far been appointed and that was by the Privy Council in 1926.

The Council's offices are at 44, Hallam Street, Portland Place, London, W.1, and it has Branch Offices at 12, Queen Street, Edinburgh and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal functions are three. First, to keep the *Medical Register*; second, to see that the name of no person is entered thereon as qualified unless he has had an adequate professional education, and to remove therefrom the names of qualified persons who are no longer entitled to public confidence; and third, to provide for the publication of the *British Pharmacopoeia*. It is the appearance of a name upon the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person a duly or legally qualified practitioner of medicine.

The Council has no power to make rules in regard to the medical curriculum or examination but it can pass resolutions and make recommendations relating thereto, and, if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which if it thought fit might order that the qualifications obtained from such bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is proved

before the Council itself to have been guilty of "infamous conduct in a professional respect," may be erased from the *Medical Register*.

The Medical Acts prohibit attempts being made to impose restriction as to any theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any 'theory' of medicine or surgery in which he honestly believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully and falsely" assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives and the Dentists Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law, they cannot hold an appointment as a medical officer in the Military or Naval Services, or on ships, they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, certificate of death, and they cannot obtain dangerous drugs.

An account of the recommendations that the Council has drawn up in respect of the education of medical students here follows.

REGISTRATION OF MEDICAL STUDENTS

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given on page 377.

Candidates must produce evidence (a) that they have attained the age of 17 years, (b) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom, and in addition thereto that they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales or Scotland, or Ireland. It must be made on a special form, which can be obtained from one of the offices of the General Medical

Council itself or from one of the various licensing bodies and medical schools

The regulations with regard to registration apply equally to medical and dental students, with the exception that, in the case of the latter, pupils who with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

PROFESSIONAL EDUCATION

The rule is that it is only from the date which appears in the Students Register that the medical student's career officially begins, thereafter five years at least must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study, and in every course the following subjects should be included

(i) Elements of General Biology including an introduction to Embryology. This course if the Licensing Bodies permit may be taken before registration and the examination may be passed immediately after registration

(ii) Chemistry Physics and Biology in their application to Medicine

(iii) Human Anatomy and Physiology including Histology Elements of Embryology Biochemistry and Biophysics

(iv) Elementary Bacteriology prior to regular clinical appointments

(v) Pathology general special and clinical and Morbid Anatomy

(vi) Pharmacology and Materia Medica to be taken concurrently with clinical instruction

(vii) Forensic Medicine, Hygiene, and Public Health

(viii) Medicine, including Applied Anatomy and Physiology Clinical Pathology and Therapeutics Children's Diseases Acute Infectious Diseases, Tuberculosis Mental Diseases Skin Diseases and Vaccination

(ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology Anaesthetics, Diseases of the Eye Ear Throat and Nose Radiology, Venereal Diseases and Orthopaedics.

(x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied

The first two years must be passed at a university, or at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body

SPECIAL CONSIDERATIONS

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order

(1) Pass an examination in arts

(2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry

(3) Having attained the age of 17, enter himself at a university or at a medical school recognized by one of the licensing bodies

(4) Obtain registration as a medical student

(5) Study for a minimum of five years certain prescribed subjects

(6) Meanwhile pass sundry intermediate examinations and at the end of the fifth year pass a qualifying examination which will entitle him to receive from a licensing body a legal authority to practise

The Minimum Period—It must be remembered that the period of five years is a minimum, more is often required even by the man of good abilities and reasonable industry, and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years or fifty-seven months, must have a considerable amount of good luck, in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance before presenting himself for any examination he must be "signed up" for the subjects covered by that examination this means that his teachers have to certify

that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place he may miss enough of them to make it impossible for him to be signed up. Then, again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on, in other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S. Eng—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

MEMORANDUM ON STUDENTS' REGISTRATION

The following memorandum has been drawn up by the Registrar of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students

The requirements for the registration of medical and dental students are the same and every intending student should in his own interest register as soon as he commences his professional curriculum

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in fulfilment thereof. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland and Ireland, the Society of Apothecaries of London and the Apothecaries Hall of Dublin) any of the examinations indicated below will be accepted. The subjects required are (1) English, (2) Mathematics (elementary) (3) a language other than English and (4) a fourth subject as required by the regulations of the particular examination to be chosen from the following—namely History Geography Physical Science Natural Science Latin Greek, Hebrew French German, or other language accepted by a university for matriculation.

The requirements of the preliminary examination in general education being satisfied it is then necessary for the student to pass a further or Pre-Registration Examination (theoretical and practical) in Elementary Chemistry and Elementary Physics which is conducted or recognised by one of the licensing bodies—that is a university or licensing corporation. These subjects must be passed in addition to those included in the preliminary examination—for example chemistry taken as one of the four required subjects in the preliminary examination cannot also count as one of the subjects of the Pre-Registration Examination. These subjects may be studied at a university or medical school or at a secondary school or other institution recognized by the body whose pre-registration examination it is intended to take. The student should in every case write beforehand to the body whose qualification he desires to obtain (a list will be found on page 377) for information in regard to its requirements for this examination.

These two examinations (in general education and in physics and chemistry) having been passed and the student having attained the age of 17 years he should apply to one of the universities or one of the medical schools for admission to its course of medical study. When medical study has been begun he should apply to the Dean of the school or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years and the dental curriculum for at least four years from the date of registration as a student.

A student who has before registration studied the subject of elementary biology at an institution recognized by one of the licensing bodies may if the body sees fit be admitted to the professional examination in this subject immediately after his registration as a student. For information in regard to this he should apply to the body whose medical qualification he seeks.

A dental student may commence his curriculum if he so desires as a pupil in dental mechanics of a registered dental practitioner but study at a dental school is to be preferred. If however he is apprenticed to a dental practitioner he will have to devote twice as much time to instruction in dental mechanics as he would if he had taken this subject in a school. This will have the effect of lengthening the curriculum. In any case a student can only obtain a concession of twelve months out of the four years curriculum.

The addresses of the Branch Registrars are

General Medical Council, 44, Hallam Street, Portland Place
London, W.1

Scottish Branch Council 12 Queen Street Edinburgh

Irish Branch Council 35 Dawson Street Dublin

Examining Bodies in Preliminary Education

The following is a list of the officials of the examining bodies in preliminary education with the names of the examinations in parentheses

Registrar Queen's University of Belfast Belfast. (Matriculation)
Registrar The University of Birmingham Birmingham. (Matriculation)
Registrar The University Bristol Bristol. (Matriculation School Certificate or Higher School Certificate)
Assistant Registrar The University of Cambridge Cambridge. (School or Higher School Certificate)
Medical Registrar University of Cambridge Cambridge. (School or Higher School Certificate)
Registrar University of Durham Durham. (Matriculation)
Registrar Irish Conjoint Board Royal College of Surgeons Dublin. (Preliminary Examination)
Registrar National University of Ireland Dublin. (Matriculation)
Joint Commissioners Intermediate Education Board of Ireland 1 Ilwme Street Dublin. (Leaving Certificate)
Assistant Secretary Ministry of Education Belfast. (Senior Grade Leaving Certificate)
Academic Registrar The University of London South Kensington London S.W.7. (Matriculation General or Higher School Certificate)
Secretary Northern Universities Joint Matriculation Board 315 Oxford Road Manchester. (Matriculation School or Higher School Certificate)
Registrar University Registrar Oxford. (Responsions)
Secretary Oxford Cambridge Schools Examination Board Schools Examination Office Balliol College Oxford. (School or Higher School Certificate)
Secretary Oxford Local Examinations University Press Oxford. (School or Higher School Certificate)
Secretary College of Preceptors Bloomsbury Square London W.C.2. (Senior Certificate)
Secretary Educational Institute of Scotland 47 Moray Place Edinburgh. (Preliminary Medical Certificate)
Secretary Scottish Education Department 14 Queen Street Edinburgh. (Leaving Certificate)
Secretary Scottish Universities Entrance Board 81 North Street St. Andrews. (Scottish Universities Entrance Examination)
Registrar University of Wales Cathays Park Cardiff. (Matriculation)
Clerk Central Welsh Board Cardiff. (School or Higher School Certificate)

[Note—School Certificates other than Higher must show Credits in each of the prescribed subjects]

Licensing Bodies

The following is a list of the officials of licensing bodies and their addresses

Secretary English Conjoint Board 8 Queen Square Bloomsbury W.C.1.
Clerk Society of Apothecaries 11, E.C.4
Registrar The University of London South Kensington S.W.7
Principal Officer University of London South Kensington S.W.7
Registrar Victoria University Manchester
Registrar The University Birmingham
Registrar The University Liverpool
Registrar The University Leeds
Registrar The University Sheffield
Registrar The University Bristol
Registrar University of Wales Cathays Park Cardiff
Secretary Scottish Conjoint Board, 48 Lauriston Place Edinburgh
Dean of the Faculty of Medicine The University Edinburgh
Registrar The University Glasgow
Registrar Royal Faculty of Physicians and Surgeons Glasgow (Dental)
Secretary The University St. Andrews
Secretary Irish Conjoint Board Royal College of Surgeons Dublin
Registrar Apothecaries Hall of Ireland 85 Merrion Square Dublin
Medical Registrar The University Trinity College Dublin
Registrar National University of Ireland University College Dublin
Registrar Queen's University Belfast

Medical Schools

The following is a list of medical schools (other than universities) and their officials

Registrar College of Medicine Newcastle-on-Tyne
Dean of the Medical College St. Bartholomew's Hospital London E.C.1.
Dean of the Medical School Charing Cross Hospital W.C.2.
Dean of the Medical School St. George's Hospital S.W.1.
Dean of the Medical School Guy's Hospital S.E.1.
Dean of the Medical School King's College Strand W.C.2.
Dean of the Medical School King's College Hospital S.E.5.
Dean of the Medical College London Hospital E.1.
Dean of the Medical School St. Mary's Hospital W.2.
Dean of the Medical School Middlesex Hospital W.1.
Dean of the Medical School St. Thomas's Hospital S.E.1.
Dean of the Medical School University College Hospital W.C.1.
Dean of the Medical School Westminster Hospital S.W.1.
Dean of the School of Medicine for Women 8 Hunter Street W.C.1.
*Registrar University College Aberystwyth
*Registrar University College Bangor
*Registrar University College Cardiff
Dean of the Medical School Welsh National School of Medicine Cardiff
Dean of the Medical School University College Swansea
Dean of the Medical School University College Dundee
Dean School of Medicine of the Royal Colleges Surgeons Hall Edinburgh
Dean St. Mungo's College Glasgow
Dean Anderson's College of Medicine Glasgow
Registrar Queen Margaret College Glasgow
Medical Registrar University of Dublin Trinity College, Dublin.
Registrar University College Cork
Registrar University College Dublin
Secretary School of Medicine Royal College of Surgeons Dublin.
Registrar University College Galway
*First year only

Dental Schools

The following is a list of dental schools and their officials in Great Britain and Ireland

Belfast Dean of the Medical Faculty Queen's University
Birmingham Dean of the Dental Hospital 132, Great Charles Street.
Bristol Dean of the Medical Faculty The University
Dublin
Medical Registrar University of Dublin Trinity College.
Registrar Schools of Surgery Royal College of Surgeons in Ireland.
Dunelm Dean of the Dental School 27 Tay Street
Exinburgh Dean of the Dental School 31 Chambers Street
Glasgow Dean Incorporated Dental Hospital and School Dalhousie Street
Leeds Dean of the Medical Faculty The University
Liverpool Director of Dental Education School of Dental Surgery Boundary Place.
London
Dean of the Dental School Guy's Hospital, London Bridge S.E.1.
Dean of the Medical School King's College Hospital Denmark Hill, S.E.5.
Dean of the Dental School London Hospital Turner Street Mile End E.1.
Dean Royal Dental Hospital Leicester Square W.C.2.
Sub-Dean for Dental Students, University College Hospital Medical School University Street Gower Street W.C.1.
Manchester Dean of the Dental School Oxford Road.
Newcastle Dean of the Dental School Handvalde Buildings Percy Street
Sheffield Secretary Board of Dental Studies The University

PROFESSIONAL EXAMINATION

The Council's Recommendations

The following recommendations of the General Medical Council in regard to professional examinations for medical and surgical qualifications were adopted in May, 1922

1 In order to secure due continuity and sequence in medical study two or more Professional Examinations in the earlier subjects should be held antecedently to the Final Examination in Medicine, Surgery and Midwifery

2 Three years at least should intervene between the date of passing the Professional Examination in Anatomy and Physiology and that of admission to the Final Examination in Medicine, Surgery, and Midwifery

3 A candidate remitted in any subject of a Professional Examination should, before he is readmitted to examination therein be required to produce satisfactory evidence that he has during the interval of remission pursued the study of the subject in which he was rejected. Candidates who obtain less than 30 per cent of the marks in any subject should be remitted for a longer period than three months.

4 In all the Professional Examinations sufficient time should be assigned to practical work in order to test the thoroughness of the candidate's knowledge and to encourage practical methods of study

5 Candidates in all their examination work should be carefully supervised

6 Two examiners should always participate in the oral examination of a candidate except in subordinate parts of practical examinations

7 In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject

8 In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question

9 It is desirable that examiners and in particular those for the Final Examination in Medicine, Surgery, and Midwifery, should be appointed or re-elected for at least three consecutive years

10 Whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50.

11 In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination.

12 The Final Examination in Medicine, Surgery, and Midwifery, with the exception of the Clinical and Practical Examination in Midwifery and Gynaecology, must not be passed before the close of the fifth academic year of medical study.

13 The three portions of the Final Examination in Medicine, Surgery, and Midwifery should not be further subdivided into sections which may be entered for or passed separately.

14 Compensation in respect of marks as between the three different portions of the Final or Qualifying Examination—namely, Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1886).

15 The Final Examination should include clinical and practical examinations in Midwifery and Gynaecology.

16 The clinical examination in Medicine, Surgery, and Midwifery should be held in properly equipped hospitals or examinations halls well provided with suitable patients.

17 In the examinations in clinical medicine at least one hour, and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case.

18 In Medicine, in Surgery, and in Midwifery no candidate should be allowed to pass who fails to obtain 50 per cent of the aggregate marks assigned to the whole examination, or who fails to obtain 50 per cent of the marks assigned to the clinical examination, or who fails to obtain 40 per cent of the aggregate of the marks assigned to the written and oral examination. In Midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination and no candidate should be allowed to pass who fails to obtain 50 per cent of the aggregate marks assigned to Clinical and Practical Midwifery and Gynaecology.

19 The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy and prescription writing, and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens.

20 At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination.

21 Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

This section of the Educational Number would be incomplete without brief mention of the memorandum, drawn up by the Registrar of the General Medical Council, on the procedure to be adopted by those who desire to enter the profession of medicine, to which reference is made in the introductory article at page 370. This pamphlet (price 1s post free) sets out in plain language the information for which the Registrar is often asked by prospective medical students or their guardians.

The English Universities.

THERE are eleven universities in England and Wales and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales whose constituent colleges are those of Aberystwyth, Bangor, Cardiff and Swansea. This university grants degrees and has laid down a six years' curriculum for candidates for the MB and BCh degrees, and it now provides at the Welsh National School of Medicine at Cardiff, instruction in all the subjects of the medical curriculum.

UNIVERSITY OF OXFORD

THE professional degrees conferred by this university are those of Bachelor of Medicine (BM), Bachelor of Surgery (BCh), Doctor of Medicine (DM), and Master of Surgery (MCh). It also grants a Diploma in Public Health and a Diploma in Ophthalmology. On receiving the BM the candidate is entitled to registration by the General Medical

Council. In favourable circumstances this degree and the BCh may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (BA), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for the subjects chosen for the arts course may be to a great extent the same as those in which examinations would in any case have to be passed for the medical degree, and the courses are dovetailed together.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St Hugh's College, St Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except those in divinity, under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

There are numerous avenues to the BA degree, but that which constitutes the normal course for medical students, as being the most closely related to their medical studies, is the following. By passing Responsions (or one of the examinations which are accepted as equivalent), the Scripture examination, some of the preliminary examinations in the Natural Science School,¹ in the first public examination, and one of the final honour examinations in the Final Honour School of Natural Science—Physiology being that usually taken.

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university; a final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively, the preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

PROFESSIONAL DEGREES

To obtain the BM, BCh degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First BM and the Second BM. These take place twice a year: the first on the Thursday, the second on the Wednesday of the eighth week of Michaelmas and Trinity terms. Every candidate at the First BM is examined in human anatomy, in physiology and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation unless he be already a registered medical practitioner, and not until a period of at least thirty-three months has elapsed from the date of his passing the first examination, and he must pass in all the three subjects at one and the same time.

Before admission to the Second BM examination the student must produce certificates of instruction from a medical school recognized by the university, of having acted as clinical clerk and dresser, each for six months and as *post-mortem* clerk for three months, of attendance on labours of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and

¹ The four subjects of the medical preliminary examination are four of the subjects in the natural science preliminary and can be commenced directly after passing Responsions.

² Membership is constituted by Matriculation and by becoming either a member of a College or a Hall or a non-collegiate student.

the administration of anaesthetics,¹ and of three academic years of hospital attendance. He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

D M AND M CH DEGREES

A Bachelor of Medicine who wishes to proceed to the D M must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M Ch he must have entered his twenty-first term and must pass an examination, which is held in June.

D PH AND D O

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas terms, that for the Diploma in Ophthalmology is held annually in March. For the Diploma in Ophthalmology attendance on a twelve months' course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

TEACHING

The several colleges provide their undergraduate members with tutors for all examinations up to the B A degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B M, and those of the Final Examination.

SCHOLARSHIPS

Most colleges grant scholarships open to intending medical students of the maximum value of £100 a year tenable for four years in natural science, chemistry, physics and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges from the principals of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year tenable for two years is conferred annually; candidates must have taken the B M degree. A Schorstein Research Fellowship of £200 a year for two years is awarded biennially. The Fellow must engage in research in one of the Medical Departments of the University. A George Herbert Hunt Travelling Scholarship of about £100 is awarded biennially to enable a young medical graduate to spend three months abroad in medical study. A Philip Walker Studentship in Pathology of £200 a year tenable for two years is awarded biennially for the encouragement of research in pathology as also are the Rolleston Memorial Prize and the Radcliffe Prize (£50) for research in natural science (including pathology), and the three Theodore Williams Scholarships in Anatomy, Physiology and Pathology of the value of £50 each tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year open to the University is awarded annually by the Master and Fellows of University College. A Burney Leo King College Hospital Scholarship of £80 is awarded annually.

FEES

An annual fee of £4 10s. is paid to the university for the first four years being reduced to £1 when the B A has been taken. For the degree the fees are the B A £7 10s. the B M and B Ch £14 the D M £25 the M Ch £12. College fees varying in amount are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £180 or for women not less than £140.

For further information application may be made to Dr E W Ashley Walker, Dean of the School of Medicine, University of Oxford.

UNIVERSITY OF CAMBRIDGE

THE professional degrees given by this university are those of Bachelor of Medicine (M B) and Bachelor of Surgery (B Chir), each of which entitles the possessor to admission to the *Register* by the General Medical Council and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants Diplomas in Tropical Medicine

¹ For the certificates that will be required from candidates amenable to the new Regulations of the General Medical Council see *Examination Statutes* Clarendon Press, Oxford 1925 edition.

and Hygiene, in Public Health, in Hygiene, and in Medical Radiology and Electrology to medical practitioners, not necessarily graduates of the university. Information regarding these diplomas will be found in later sections under the headings Tropical Medicine, Public Health, and Radiology. A candidate for the M B, B Chir degrees need not possess a degree in arts, it is sufficient if he has passed the Previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B A degree, preferably by obtaining honours in the Natural Science Tripos at the end of their third year. The attainment of a sufficient standard in certain subjects in this Tripos will secure exemption from the corresponding tests in the First and Second M B examinations. Members of Girton College and Newnham College are now admitted to the M B examinations.

PROFESSIONAL EXAMINATIONS

To obtain the M B degree the candidate must pass three examinations and keep an Act. The B Chir degree (which is a registrable qualification) may be obtained after passing all three examinations.

First M B—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary biology. The parts may be taken together or separately. In either case the candidate, before admission to examination, must have satisfied the requirements in respect of the Previous examination and have paid the registration fee. Certain exemptions from the First M B Examination are allowed, the regulations may be obtained from the Registrar. The examination is held three times in the year.

Second M B—This examination comprises Part I, organic chemistry, Part II, human anatomy and physiology, Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No student is admitted to the first part of the Second Examination until he has passed the first part of the First Examination. No student is admitted to the second part of the Second Examination until he has passed all parts of the First Examination. No student shall be admitted to the third part of the Second Examination until he has passed the first and second parts of the Second Examination. The candidate must present certificates of study in the subjects of the second and third parts. The examinations for Part I are held in October, December, and June, and for Part II in December and June, that for Part III in October and April.

Third M B—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and he signed up in these subjects and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. The examination is in the principles and practice of physics (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine) and pharmacology (including therapeutics and toxicology). The Third M B examinations are held twice a year—in June and December.

Act for the M B—Before receiving his M B degree a candidate who has passed the Third M B examinations has to write a thesis. This he reads in public on an assigned day and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physics. If approved at this test he is then certified as having "kept the Act satisfactorily and in due course receives his degree. Medical degrees may be taken in absence by those living abroad the candidate sending to the Regius Professor of Physics a dissertation, which is laid before the Degree Committee.

THE HIGHER DEGREES

The M D degree may be taken by a Bachelor of Medicine of three years' standing (and a Master of Arts of four years' standing).

standing who has completed the course required for M B) after writing a thesis approved by the M D Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the Act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

A candidate for the M Chir degree who is an M A may be admitted to the examination after he has become legally qualified to practise surgery. Other candidates may be admitted when two years have elapsed after they have passed the Third M B Examination. The examination comprises pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical; they include the writing of an extempore essay.

FEES

In addition to college fees, tutorial fees, and the expense of living, the following examination fees are payable: First M B £5 5s, Second M B, £6 6s, Third M B £10 10s. For schedules referring to the examinations lists of schools recognized by the university, and other information application should be made to the University Registry, Cambridge.

UNIVERSITY OF LONDON

UNDER the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in four branches, Doctor of Medicine in six different branches, Bachelor of Dental Surgery, and Bachelor of Pharmacy. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days, the first two take place both in London and in certain provincial centres, the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the matriculation examination or obtained registration in some other way, and, unless they are already registered medical practitioners of a certain age and standing, all medical students must pass not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

PROFESSIONAL EXAMINATIONS

M B, B S—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I cannot be passed within six months of the passing of the First Examination. It covers organic chemistry, the candidate's knowledge being tested as in the earlier examination. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M B, B S Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including mental diseases), pathology, forensic medicine and hygiene, surgery, and obstetrics and gynaecology. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and obstetrics and gynaecology. Either group may be taken first at the option of the candidate

or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES

M D—An examination for the M D is held twice yearly—in December and July. Every candidate must have passed the examination for the M B, B S, unless he became M B before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M B and sitting for the M D in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen, both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M D Examination a gold medal of the value of £20 may be awarded.

M S—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are four branches in which it may be obtained—General Surgery, Dental Surgery, Ophthalmology, and Laryngology, Otology, and Rhinology.

FEES

For Matriculation 2½ guineas for each entry. First Examination 6 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination Part I 3 guineas for the first and each subsequent entry. Second Examination, Part II 9 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M B, B S Examination 12 guineas for each entry to the whole examination, and 6 guineas for examination or re-examination in either group. M D and M S Examinations 20 guineas and 10 guineas on re-examination.

Inquiries should be addressed to the Academic Registrar the University of London, South Kensington, S.W.7.

UNIVERSITY OF BIRMINGHAM

THIS university confers medical and surgical degrees—namely, M B, Ch B, M D, and Ch M—and also diplomas and degrees in State medicine and dentistry. The M B, Ch B candidate may also combine with the earlier part of his medical curriculum courses leading to the ordinary B Sc degree in Anatomy and Physiology. The degree of B Sc with Honours in one of these subjects requires an extra year. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M B (Part I) those who have passed elsewhere an examination considered to be its equivalent. A degree of Ph D is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M B, Ch B degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham, or (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation exam is held in July and September. The regulations and the

list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester

(2) A recognized pre-medical examination in the subjects of chemistry and physics—for example, the Higher School Certificate of the Joint Matriculation Board, or a candidate may attend courses for pre-medical year in the university, October to June, taking chemistry and physics, and biology (optional)

For and after the session 1929-30 the passing of an examination in elementary biology will be compulsory before a student reading for the M B, Ch B Birmingham, or for any medical or dental degree or diploma in which an examination has to be passed in this subject, can enter the Faculty of Medicine

PROFESSIONAL EXAMINATIONS

The candidate for the M B, Ch B degrees has five examinations to pass. In the Second and Final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again

The First M B (Part I) deals with elementary biology and physical and organic chemistry. The First M B (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Second M B deals with pathology and bacteriology, materia medica, and pharmacy. The Third M B takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, and pharmacology and therapeutics

Final M B—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a *post-mortem* clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerkship, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others

M D—An ordinary candidate for this degree must be a M B, Ch B of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch M are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M D and Ch M in the same way as holders of the Birmingham M B, Ch B

FEES

The fee for matriculation is £2 (payable to Joint Matriculation Board) £2 10s for pre-medical examination (if taken in university) and £2 10s for each of the first four professional examinations. M B, Ch B degree fee £10. M D and Ch M examinations £12 10s each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham

UNIVERSITY OF BRISTOL

In the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), Bachelor of Dental Surgery (B D S), and Master of Dental Surgery (M D S). There are also the following diplomas: diploma in public health (D P H), diploma in dental surgery (L D S), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to reach matriculation standard in the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery—Candidates must be not less than 21 years

of age and have pursued the courses prescribed by university regulations, during not less than five years after passing the first examination in chemistry and physics, of which three shall have been spent in the university, and two of these three subsequent to passing the second examination. All candidates for the degrees of M B, Ch B are required to satisfy the examiners in the several subjects of three examinations

The First Examination—The subjects of examination are chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B Sc curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study)

The Second Examination—The subjects of examination are organic chemistry and elementary anatomy (Part I) and advanced anatomy and physiology (Part II)

The Final Examination—The subjects of examination are materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I), special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative, including ophthalmology and oto-rhino-laryngology), medicine (systematic, clinical, and practical, including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I, surgery and obstetrics, Group II, medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately, but no student can obtain honours who elects to take the two groups of Part II separately. Forensic medicine and toxicology may be taken either with Part I or with Group II of Part II

Degree of Doctor of Medicine—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a diploma in public health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof

Degree of Master of Surgery—Candidates shall be Bachelors of not less than two years' standing as such during which period they shall have attended the surgical practice of an institution approved for the purpose. They shall pass an examination in surgical anatomy, pathology, and bacteriology, and operative, clinical, and general surgery and present to the university a dissertation on some subject of surgery. The degree may be taken also in general surgery, and a special subject—for example, oto-rhino-laryngology, ophthalmology and gynaecology

Diploma in Public Health—Candidates must be at least 23 years of age, be fully registered medical practitioners of not less than two years' standing as such and have passed the examination prescribed by regulation. The examination is divided into two parts

UNIVERSITY OF DURHAM

To its own undergraduates who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M B, B S), and Doctor of Medicine (M D), Master of Surgery and Doctor of Surgery (M S and D Ch), Bachelor of Hygiene, Doctor of Hygiene, and Bachelor of Dental Surgery and Master of Dental Surgery (B D S and M D S), it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University School Certificate Examination (if a sufficient standard is obtained in certain specified subjects) for matriculation purposes but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to

satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts. It is sufficient if, before he presents himself for his final examination, the candidate has spent at least one year in study at the University of Durham College of Medicine, Newcastle-on-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere.

PROFESSIONAL EXAMINATIONS

There are four professional examinations for the M.B., B.S. degrees. The First, Second, and Third Examinations are held in March and June, and the Final Examination in June and December. The first deals with biology and organic chemistry, the second with anatomy and physiology, the third with pathology, bacteriology, materia medica, pharmacology, general principles of therapeutics, and pharmacy, medical jurisprudence, and public health. At the Final M.B., B.S. the candidate is examined in medicine and clinical medicine, surgery and clinical surgery, midwifery and diseases of women and children, clinical and practical midwifery and gynaecology, and clinically in psychological medicine, diseases of the throat, nose, and ear, diseases of the skin, diseases of the eye, and diseases of children.

U.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not an M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 425.)

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

D.Ch.—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and ancillary subjects, one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Degree of Bachelor of Hygiene and the D.P.H.

No candidate is admitted to the final examination for the degree of B.Hy. unless he is a Bachelor of Medicine and Surgery of not less than two years' standing of a recognized university whose degrees are registrable on the books of the General Medical Council of the United Kingdom.

No candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner of not less than two years' standing.

The course of study for the B.Hy. and D.P.H. extends over a period of not less than twelve calendar months subsequent to the attainment of a qualification registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham or at any medical school or institution which is recognized by the university.

The examination for the diploma or degree consists of Part I and Part II each of which extends over not less than two days and is conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to

examination for Part II. In Part I, and also in Part II a candidate must pass in all the specified subjects at one time.

The examination for Part I is practical, written and oral and includes the following subjects: bacteriology and parasitology (including medical entomology), chemistry and physics, and meteorology and climatology in relation to public health. Candidates are not admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof.

The examination for Part II includes the following subjects: hygiene and sanitation (including sanitary construction), epidemiology and infectious diseases, sanitary law and vital statistics, public health administration. The examination is written and oral, and includes practical examinations in infectious diseases, food inspection, inspection of premises—dwellings, factories, workshops, schools, etc. Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

Doctor of Hygiene

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of the university of two years' standing and are required to satisfy the examiners that they have conducted original research in the subject of public health.

Diploma in Psychiatry

Candidates must be registered medical practitioners and, unless qualified before January 1st 1911, must have attended subsequent to passing their qualifying examinations, courses of instruction in (a) anatomy, (b) physiology, (c) pathology, (d) bacteriology, (e) psychology and experimental psychology, (f) clinical neurology, (g) psychiatry, (h) clinical psychiatry. The examination consists of two parts, namely (1) anatomy, physiology, pathology and bacteriology, (2) psychology and experimental psychology, neurology and psychiatry (systematic and clinical) and candidates may present themselves for the whole examination or for either part separately.

Licence and Degrees in Dental Surgery

L.D.S.—Every dental student must at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.

The First Examination consists of three parts which may be passed separately: Part 1 organic chemistry, Part 2 biology, Part 3 theoretical dental mechanics, dental metallurgy (theoretical and practical). Second Examination: Anatomy, physiology (including biochemistry and biophysics), dental anatomy, and dental histology. Third Examination: Pathology and bacteriology, practical dental mechanics, dental materia medica and therapeutics. Final Examination: Medicine, surgery, dental surgery and pathology, orthodontics, operative dental surgery and dental prosthetics, and anaesthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects, attended after registration as a dental student at recognized colleges or medical schools.

Degree of Bachelor of Dental Surgery—1—Students taking their complete course of instruction in the university must pass the same matriculation tests as medical students, and the same pre-registration examination in inorganic chemistry and physics. After registration students must spend five years in the university. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years, six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations. The subjects of the examinations are as follows: *First* Biology, organic chemistry, and dental mechanics and metallurgy. *Second* Anatomy, physiology, dental anatomy and histology. *Third* Pathology and bacteriology, dental materia medica and therapeutics, and practical and dental mechanics. *Final* Medicine, surgery, dental surgery and pathology, orthodontics and operative dental surgery. In this subject knowledge of a much higher standard, and more advanced practical work are required than for the Licence in Dental Surgery.

2—Candidates possessing a Licence in Dental Surgery of a British university must study for at least one year in the university. During such year they must (a) attend a course of instruction in pathology and bacteriology and (b) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery—Every candidate for this degree must be a Bachelor of Dental Surgery of the university of not less than two years' standing and present an essay embodying original work and research in some subject connected with dentistry. He must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations.

The practical examinations in dentistry are conducted at the Newcastle-upon-Tyne Dental Hospital.

FEES

The following fees are payable: Matriculation £2. Examinations, First, Second, and Third M.B., B.S. each £5. Final M.B., B.S. £15. M.D. and M.S., each £5. B.Hy., D.P.H. and D.S., each £10. 10s. and D.Hy. and D.Ch. each £20. First, Second, and Third L.D.S. each £5. 10s. and Final L.D.S. £5. First, Second, and Third B.D.S. each £5. Final B.D.S. £8. and M.D.S. £5. For degrees and diplomas: M.B., B.S., B.Hy., and B.D.S. each £6. 6s. plus

the sum of 10s if it is the initial degree taken in the university M.S. and M.D.S., each £6 6s. M.D., D.Ch. and D.Hy., each £10, D.P.H., D.Psy., and L.D.S., each £3

Further information may be obtained from the Dean of the College, University of Durham College of Medicine, Newcastle-on-Tyne

UNIVERSITY OF LEEDS

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychology, in dental surgery, and in nursing.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in

I Either English Composition and English Literature, or English Composition and History

II Either Mathematics or Latin

III } Three other subjects not already taken under I and II above,
IV } chosen from the following list
V }

- | | |
|---|---------------------------------|
| 1 English Literature | 9 Mathematics |
| 2 History | 10 Mechanics |
| 3 Geography | 11 Physics |
| | 12 Chemistry |
| 4 Greek | 13 General Experimental Science |
| 5 Latin | |
| 6 French | 14 Natural History |
| 7 German | 15 Botany |
| 8 Some one other language approved by the Board | |

Provided that (a) candidates who take Mathematics under II above must include one of the subjects 4-8 (b) candidates who take Latin under II above must include one of the subjects 9-15 In all cases Mathematics is a compulsory subject for admission to the Faculty of Medicine

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination

PROFESSIONAL EXAMINATIONS

The examinations for the M.B., Ch.B. number three. The first deals with (1) Physics and Chemistry, (2) Biology. In each subject laboratory work is included but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

The Second Examination—The Second Examination consists of Part I, Organic Chemistry, Part II, Materia Medica and Practical Pharmacology, Part III, Anatomy and Physiology, Part IV, Pharmacology. Candidates will be allowed to pass any parts separately.

The Final Examination—The Final Examination consists of Part I, Pathology and Bacteriology, Part II, Medicine, Surgery, Obstetrics, Gynaecology, and Clinical Pathology, Part III, Forensic Medicine, Public Health, and Therapeutics. Part I may be taken at the end of the second clinical year, and must be passed before Parts II and III are taken. Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. If taken separately Part II must be passed before Part III.

M.D.—A candidate for this degree must be a M.B., Ch.B. of the university, of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses,

including one on ophthalmology and one on bacteriology, he is then examined on the subject of surgery in all its branches.

FEES

The matriculation fee is £2 and on readmission £1 10s. For each of the other examinations £6 and £5 on readmission. Ch.M. £10 and same on readmission. M.D. £10. On conferment of the degree of Ch.M. £5 is payable, and £5 for the M.D. degree.

UNIVERSITY OF LIVERPOOL

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.), gives degrees in dental surgery (B.D.S. and M.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), tropical hygiene (D.T.H.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrolgy (D.M.R.E.). The degree of Doctor of Philosophy (Ph.D.) may also be taken in the Faculty of Medicine.

MATRICULATION

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester which accepts, under certain conditions, the tests of several other bodies as its equivalent. Chemistry and physics are essential pre-registration subjects.

It should be particularly noted that important alterations in regard to Matriculation requirements and the first and second years' courses of study will come into operation in October, 1929. Particulars may be obtained on application to the Dean.

PROFESSIONAL EXAMINATIONS

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, (2) physics, (3) biology (zoology and botany).

Second M.B.—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology, and (b) (3) elementary bacteriology, (4) clinical chemistry, (5) general pathology. Candidates may present themselves in (a) and (b) separately.

Final M.B.—The subjects of the Final Examination are (a) (1) special pathology and morbid anatomy, (2) forensic medicine and toxicology, (3) public health, (4) pharmacology and general therapeutics, (b) (5) obstetrics and diseases of women, (6) surgery—systematic, clinical, operative, and practical—including ophthalmology, (7) medicine—systematic and clinical—including therapeutics, mental diseases, and diseases of children. Candidates may take Parts (a) and (b) separately but Part (b) may not be taken until five years of study have been completed.

M.D. and Ch.M.—Candidates for these degrees must have received the M.B. and Ch.B. (Liverpool) at least two years previously. The M.D. candidate submits for approval a thesis covering original work in some branch of medicine or some science directly relative to medicine together with, if desired, copies of published work, if the thesis is not judged to be of special merit an examination in either Medicine or some subject connected with the thesis is required. The Ch.M. candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 399.

FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in Anatomy two each of the value of £120 tenable for two years. (2) Ethel Bovee Fellowship in Gynaecology value £100 and tenable for one year open to fully qualified medical students of either sex. (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology two in number value £150 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology value £150 and tenable for one year. (8) Lady Jones Fellowship in Orthopaedic Surgery etc. value £200 offered every two years.

There are in addition scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER

This university grants the four ordinary degrees in medicine and surgery—MB and Ch B and M D and Ch M, a degree and diploma in dental surgery, a diploma in public health, a certificate in factory and in school hygiene, a diploma in psychological medicine, and a diploma in bacteriology. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof, see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M B Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) one subject at choice as approved by the Joint Board. It is held in July and September.

PROFESSIONAL EXAMINATIONS

M B, Ch B—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M B is divided into Part I, chemistry and physics, Part 2, biology—(a) botany, (b) zoology. The parts may be taken separately or together. At the Second M B the candidate is examined in anatomy (including histology) and physiology, at the third in pathology, bacteriology, and pharmacology (including materia medica and practical pharmacy). The Final Examination, under new regulations, is divided into two parts, which may be taken separately. Part I consists of (a) forensic medicine and toxicology, and (b) hygiene and preventive medicine. Part II consists of (a) medicine, including dermatology, diseases of children, and mental diseases, (b) surgery, surgical pathology, and diseases of the eye and of the ear, nose, and throat, (c) obstetrics and gynaecology.

M D—A candidate for this degree must be a Bachelor of Medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

Ch M—A candidate must have held, since becoming Ch B, and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery, Branch II, obstetrics and gynaecology, Branch III, ophthalmology, Branch IV, otology, laryngology, and rhinology.

B Sc and M Sc—The ordinary degree of B Sc in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degree of M B, Ch B complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B Sc in Anatomy or Physiology who are students in medicine are required to attend courses in advanced anatomy and physiology for four terms after passing the Second Examination for the degrees of M B, Ch B. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M Sc by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

FEES

The following examination fees are payable. Matriculation £2 on readmission, £2. Each M B examination £8 8s on readmission £5 3s. M D including the conferring of the degree £15 15s. Ch M £10 for the examination and £10 10s for conferment of degree. Application for further information should be addressed to the Dean of the Medical School.

UNIVERSITY OF SHEFFIELD

The degrees of this university (M B, Ch B, M D and Ch M, B D S, and M D S), and the diploma of licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognised for this purpose and have passed the further examination in chemistry and physics.

PROFESSIONAL EXAMINATIONS

A candidate for the degrees of M B, Ch B must produce certificates that he will have attained the age of 22 years by the day of graduation, that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation, and the passing of the further examination in chemistry and physics, three of such years at least having been passed in the university, one at least being subsequent to the passing of the First Examination. The following examinations must be passed in due order.

First Examination—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M B Examination will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B Sc Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, and the passing of the further examination in physics and chemistry, in (i) chemistry, inorganic and organic, (ii) physics, (iii) biology.

Second Examination—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study, must have passed the First Examination, and must have attended (1) courses on anatomy, including lectures and practical anatomy, during one year, (2) courses on physiology, including lectures and practical physiology during one year.

Third Examination—The subjects are pathology and pharmacology, anatomy, and physiology. Candidates must have completed the Lent term of the fourth year of medical study and the requisite courses in these subjects, including post mortem clerkship for three months.

Final Examination—The subjects are Part I, forensic medicine and public health, Part II, medicine (including mental diseases and diseases of children), surgery, obstetrics (including gynaecology). Candidates for Part I must have completed Michaelmas term of the fifth year of study, candidates for Part II must have completed the fifth year of study.

M D—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M B, Ch B at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch M—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M B, Ch B at least one year previously, and must, since taking the degrees of M B, Ch B, have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M B), Bachelor in Surgery (B Ch), Master in Surgery (M Ch), and Doctor in Medicine (M D).

A candidate for the M B, B Ch is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth, University College of North Wales, Bangor, University College of South Wales and Monmouthshire, Cardiff, and University College, Swansea. He must also hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study

pursued for a B.Sc. or a B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology, and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year, study of physiology and anatomy must extend over at least two academic years, the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year, and in medicine, surgery, obstetrics, and gynaecology in December also.

The university also offers courses of study in public health and in tuberculosis. Candidates for the Diploma in Public Health (D.P.H.) and for the Tuberculous Diseases Diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff, or at another institution approved by the university.

WELSH NATIONAL SCHOOL OF MEDICINE

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., B.Ch. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

English Medical Corporations.

THERE are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD

THIS body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P. Lond. or M.R.C.S. Eng. It performs the same task in connexion with diplomas in public health, tropical diseases, ophthalmic medicine and surgery, psychological medicine and laryngology and otology—jointly issued by the two Colleges in question. Under the new regulations, which apply to all students who did not pass the required preliminary tests of general education before January 1st 1923 every candidate for the L.R.C.P. and M.R.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics, (2) comply with the regulations which may be laid from the Secretary Examination Hall, Queen Square, London, W.C.1, and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in the Educational Number of the *British Medical Journal* for 1922 still apply to students who passed their preliminary examination in general education before January 1st 1923.

NEW REGULATIONS FOR THE CONJOINT DIPLOMA

The following is an outline of the regulations applicable to candidates for the L.R.C.P. Lond. and M.R.C.S. Eng. who passed the required Preliminary Examination in general education on or after January 1st, 1923. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

PRE-MEDICAL EXAMINATION

Students are required to pass a Pre-Medical Examination in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognized by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any university, the Board of the Higher School Certificates of Universities and the Oxford Board of the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, the Central Welsh Board Higher Certificate or the Pre-Medical Examination in Chemistry and Physics conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register.

A candidate must enter for Chemistry and Physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months.

PROFESSIONAL EXAMINATIONS

There are two Professional Examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the Pre-Medical Examination in Chemistry and Physics or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

First Professional Examination.—The subjects of this are Section I (a) Anatomy including Histology and Embryology, (b) Physiology including Biochemistry. Section II, Pharmacology, Practical Pharmacy and Materia Medica. A candidate must have attended at a recognized Medical School courses of instruction in Anatomy including Embryology during five terms, during which he must have dissected the whole body courses of instruction in Physiology including General Biology, Biochemistry and Biophysics during five terms courses of instruction in Pharmacology, Practical Pharmacy and Materia Medica. A candidate may present himself for the two sections together or separately but he must take parts (a) and (b) of Section I together until he has passed in one or both parts but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are Section I Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology) and Bacteriology. Section II Part I Medicine including Medical Anatomy, Forensic Medicine and Public Health. Part II Surgery including Surgical Anatomy and the use of Surgical Appliances. Part III Midwifery and Gynaecology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of Pathology and Bacteriology at a university recognized by the Board is exempted from Section I.

FEES

The fee for the Pre-Medical Examination is three guineas for re-examination in Chemistry two guineas and for re-examination in Physics one guinea. The fee for the First Professional Examination is ten guineas for re-examination after rejection in Section I six guineas for re-examination after rejection in either part of Section I three guineas for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the Final Professional Examination is four guineas for admission to Section II Part I ten guineas Part II ten guineas Part III six guineas and the re-examination fees are respectively three guineas six guineas and four guineas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

THIS College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or to those who are registered practitioners and graduates of a recognized university, in any case they must

be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce; they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £8 8s, payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session, the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees, which must be registrable in this country.

Fees—At first examination £8 8s, for re-examination £5 5s. At second examination £12 12s. Admission fee £10 10s. for members £31 10s. for non members.

SOCIETY OF APOTHECARIES OF LONDON

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations.

Pre-medical Examination—Chemistry and chemical physics.

Primary Examination—This includes anatomy, physiology, and histology, and materia medica and pharmacy. Candidates will be excused any or all the subjects of the Primary Examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine: (a) the principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology, (b) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the Primary Examination is £5 5s, for the Final £15 15s. The regulations and synopses relating to the several examinations and other information may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, EC 4.

Mastery of Midwifery

The Society has recently instituted a Mastery of Midwifery, and proposes to issue a diploma under this title denoting the possession of specialized knowledge of antenatal care, midwifery, and child welfare. The first examination will commence on October 15th, and candidates are required to submit certificates, etc., fourteen days before this date. It is intended to impose a severe test so as to ensure a high standard of professional knowledge, but the diploma will not be registrable under the Medical Acts. Admission is open to all who have been for not less than a

year in possession of a registrable medical qualification, and who have had certain prescribed experience at recognized institutions concerned with obstetrics, antenatal work, and child welfare work. Special conditions apply, until 1932, to practitioners of ten years' standing. The entrance fee for the examination is £5 5s, and a further fee of £5 5s is payable by successful candidates before admission to the Mastery. Copies of the regulations may be obtained from the secretary at the address given in the preceding paragraph.

The Scottish Universities.

There are in Scotland four universities, each possessing a Faculty of Medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland, here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides the degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry, public health, and radiology. As for public health, registrable degrees in this subject are granted by the University of Glasgow, while diplomas in public health may be obtained from the universities of St Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science).

As from January 1st, 1923, prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

PROFESSIONAL EDUCATION

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and, in addition, necessitate definite study for stated periods of diseases of children, of the larynx, ear, and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

PROFESSIONAL EXAMINATIONS

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinc-

tion," and a record is kept of the merit displayed, so that when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry, the second with anatomy and physiology, the third with materia medica and pathology, the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year, the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts, science, or medical degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

THE HIGHER DEGREES

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Service, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES

It is estimated that the class examination and other fees for the M.B., Ch.B. come altogether to about £256, the separate examination fees included in this calculation being as follows:

	£	s	d
First Professional	9	9	0
Second Professional	7	7	0
Third Professional	6	6	0
Final	11	11	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21 and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d, which is published by Mr. Thun, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

THE CARNEGIE TRUST

The following is a summary of the regulations made by the Carnegie Trust for the Universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 17 years of age, they must be of Scottish birth or extraction or have attended for two years after the age of 14 at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department, provided

that it bears evidence of such preliminary education as is required by the universities for their graduating curricula, or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or whose other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are Arts and Medicine—two Arts grants of £8 and four Medicine grants of £19 in all £92. Science and Medicine—two Science grants of £17 and four Medicine grants of £19 in all £110.

Applicants, in writing for application forms, must name the university and faculty in which they intend to study and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session or May 10th for the summer session. Payments are made by means of fee coupons and fees already paid are not refunded.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board, which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Ed., L.R.C.S. Ed. and L.R.F.P.S. Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

Professional Curriculum for Candidates registered as Medical Students prior to January 1st, 1923

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period, it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology, the second with anatomy and physiology, including histology, the

third with pathology and *matrimonia medica*, including pharmacy, and the final with (1) *medicina*, including therapeutics, medical anatomy, and clinical medicine, (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes, (3) midwifery and diseases of women and of newborn children, including clinical gynaecology and practical midwifery, and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates will also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the Final Examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects, but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

All candidates for the Final Examination must complete the pass in the three portions (medicine, surgery, and midwifery) within a period of nineteen months.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint licence must sit for the Final Examination and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923

The curriculum has been extended to meet the recommendations of the General Medical Council. Candidates, when applying for copies of regulations, should state date of medical registration.

FEES

It is estimated that the total cost of lectures and fees for the Conjoint licence is about £152. The separate examination fees are as follows: First Second and Third Professional £5 each; Final £15. On re-entry for any of the first three examinations £3 and on re-entry for the Final £5. If the re-entry is only in one or two subjects of the First Second or Third Examinations the fees are smaller.

Information concerning this Board should be sought either from Mr D. L. Eadie, 49, Lauriston Place, Edinburgh, or from Mr Walter Hurst, Faculty Hall, 242, St Vincent Street, Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

This College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in *materia medica*. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday and Thursday except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university, approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the

Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a Member of the College for at least three years, and, if accepted, pay fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence

As an original qualification the Licence is only granted after fulfilment of the regulations of the Scottish Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s. of which £10 10s. is returned to unsuccessful candidates. On due cause being shown a special examination may be granted, the fee being £20 of which £10 is returned to a candidate if he is not approved.

Fellowship

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials specially obtained for the purpose. Candidates are not allowed to appear more than three times at the examinations.

Licentiates of the College pay £35, and others £50. For further information application should be made to the Clerk of the College, Mr D. L. Eadie, 49, Lauriston Place, Edinburgh, from whom a copy of the *Laws Relating to the Fellowship by Examination* may be obtained.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s. and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect four Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr Walter Hurst, Faculty Hall, 242, St Vincent Street, Glasgow.

Irish Universities and Corporations.

MEDICAL REGISTRATION IN THE IRISH FREE STATE

THE Medical Practitioners Act, 1927 (Irish Free State), provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council will be (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the register and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty on the advice of the Privy Council, to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts and the powers of holding qualifying examinations and granting diplomas for the purpose of registration, in the general Register formerly vested in certain universities and medical corporations in Ireland are not affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general Register the General Medical Council and the Branch Council for Ireland shall have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general Register shall be entitled on the payment of a prescribed fee to be registered in the *Irish Free State Register*, but this fee will not be payable by any person who, on the date of the establishment of the *Irish Free State Medical Register*, is registered on the general Register. Then follow provisions with regard to the erasure from the Register of the name of a person on account of misconduct.

The Irish Free State Medical Registration Council fixed May 26th, 1928 as the last day for receiving applications without a fee, for the registration of medical practitioners in the Free State Register, whose names, at that date, were on the general *Medical Register* but whose addresses were outside the Irish Free State area. These medical practitioners are, however, still eligible for registration in the *Irish Free State Medical Register* on the payment of a fee. The names of medical practitioners with the Irish Free State addresses were placed automatically without a fee on the Free State Register. Applications for further information may be made to the Free State Medical Registration Council, Room 123, Custom House, Dublin.

THE IRISH UNIVERSITIES

THERE are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State the University of Dublin (usually known as Trinity College, Dublin) and the National University of Ireland, and, in Northern Ireland, the Queen's University of Belfast.

UNIVERSITY OF DUBLIN TRINITY COLLEGE

THIS university grants two degrees in medicine (M B and M D), two in surgery (B Ch and M Ch), two in midwifery (B A O and M A O), and a post-graduate diploma in public health. It also grants post-graduate diplomas in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve

months' study is required. The degrees are granted to those who, having passed the Professional Examination, have also graduated in arts.

PROFESSIONAL EXAMINATIONS

A candidate for the Final Examination for the M B, B Ch, and B A O degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific—This covers (a) chemistry, (b) physics, (c) botany and zoology, the three divisions may be taken together or at different times.

Intermediate Medical—This is divided into two parts (a) anatomy, physiology, organic chemistry and histology, (b) applied anatomy and applied physiology. The two parts may be taken separately or together.

Final Examination—Part I Hygiene and medical jurisprudence, pathology and bacteriology, materia medica and therapeutics. Part II (a) Midwifery and gynaecology, (b) medicine and mental diseases, (c) surgery in all branches including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

M D—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B A three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and also examine him *viva voce* on other medical subjects of a more general nature.

M Ch—The candidate must be a B Ch of not less than three years' standing and have been engaged in practice for two years.

M A O—The candidate must be a B A O of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY BELFAST

THE degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M B), Bachelor of Surgery (B Ch), Bachelor of Obstetrics (B A O), Doctor of Medicine (M D), Master of Surgery (M Ch), Master of Obstetrics (M A O). The university also confers a Diploma in Public Health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B D S and M D S) are conferred by the university, and also a diploma in dental surgery (L D S).

PROFESSIONAL EXAMINATIONS

The examinations for the M B, B Ch, B A O are four in number. The first deals with (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology (both theoretical and practical) and may be taken at the end of the second year of the student's career. The Third Examination includes (1) pathology and practical pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the

study of the subjects of this examination must show that the work has been done after the Second Examination has been passed.

The Final Examination includes (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

THE HIGHER DEGREES

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (a) human anatomy, including embryology, (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for the degrees of MCh and MAO are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.

Application for other information may be made to the Registrar, National University of Ireland, 86, St Stephen's Green, Dublin.

THE IRISH CORPORATIONS

There are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities, and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall in Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

THE CONJOINT BOARD IN IRELAND

This body requires of candidates either the passage of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in chemistry and physics and biology.

PROFESSIONAL EXAMINATIONS

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first examination deals with (a) anatomy, and (b) physiology and histology. The second examination deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics and ophthalmology, and may be taken separately.

Final Examination—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (a) medicine, including fevers, mental diseases, and diseases of children, (b) surgery, including operative surgery, (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.

Fees—Preliminary Examination £2 2s. Re-examination £2 2s. Pre-Registration Examination £3 3s. Re-examination in Chemistry £2 2s. in Physics £1 1s. First Professional Examination, £26 5s., Second, £15 15s. Final, £8 6s. Re-examination fee is £2 2s. for each division.

Diploma in Psychological Medicine

There are two examinations in connexion with this diploma. Part I consists of (a) anatomy and physiology of the nervous system, (b) psychology. Part II—(a) neurology, including clinical and pathological neurology, (b) psychological medicine, including its legal relationships.

Fees—£8 6s. for each part.

Further information can be obtained from Mr Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND

The Diploma in Public Health

Every candidate for the Diploma in Public Health must observe the following rules:

Rule 1 A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery and Midwifery and his admission to the Final Examination for a Diploma in Public Health.

Rule 2 The curriculum for the Diploma in Public Health shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

Rule 3 Every candidate shall produce evidence of having attended during a period of not less than five months at an institution approved by the Licensing Body granting the Diploma practical instruction in—

- Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man.
- Chemistry and Physics in relation to Public Health.
- Meteorology and Climatology in relation to Public Health.

At least 180 hours must be devoted to Course (a) of which not less than 150 hours shall be occupied in practical laboratory work.

At least 90 hours must be devoted to Course (b) of which not less than 70 hours shall be occupied in practical laboratory work.

At least 10 hours must be devoted to Course (c).

Rule 4 Every candidate shall produce evidence of having received during not less than 80 hours at an institution or from a teacher approved by the Licensing Body granting the Diploma instruction in the following subjects:

- The Principles of Public Health and Sanitation (30)
- Epidemiology and Vital Statistics (20)
- Sanitary Law and Administration (including Public Medical Services) (20)
- Sanitary Construction and Planning (10)

[The numbers indicate the normal proportion of time to be given to each subject.]

Rule 5 Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

Rule 6 Every candidate shall produce evidence that he has during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of Public Health Administration under the supervision of a Medical Officer of Health who shall certify that the candidate has received from this Officer or other competent Medical Officer during not less than three hours on each of sixty working days practical instruction in these duties and also those relating to

- (a) Maternity and Child Welfare Service
- (b) Health Service for Children of School Age
- (c) Venereal Disease Service
- (d) Tuberculosis Service
- (e) Industrial Hygiene
- (f) Inspection and Control of Food including meat and milk.

Certificates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who devotes his whole time to Public Health work or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50,000 or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

Rule 7 The examination for the Diploma shall be divided into two parts Part I and Part II.

Rule 8. The examination for Part I shall include the following subjects

- Bacteriology and Parasitology (Including Medical Entomology)
- Chemistry and Physics, and Meteorology and Climatology in relation to Public Health

Rule 9 The examination for Part II shall include the following subjects

- Hygiene and Sanitation (Including Sanitary Construction)
- Epidemiology and Infectious Diseases
- Sanitary Law and Vital Statistics
- Public Health Administration.

The examination shall be written and oral, and shall include practical examinations in Infectious Diseases Food inspection Inspection of premises—dwellings factories workshops schools etc.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of the Royal College of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College.

Fees—For the Licence in Medicine, 15 guineas. Special Examination £21. For the Licence in Midwifery 8 guineas. Special Examination 16 guineas. For the Membership 20 guineas to a Licentiate of the College 35 guineas to others a special examination costs 10 guineas extra. The Fellowship £35 in addition to stamp duty £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology, and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly *viva voce*, while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle

the holder to admission to the *Medical Register*, if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees—Candidates for the Licence pay 5 guineas for examination which sum, if they pass is counted as part of the fee payable on admission to the Licence this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

Fees—Primary Examination (Parts I and II) £21. Final Examination, £21. Subjects of examination Primary Part I Anatomy and Physiology. Primary Part II Materia Medica including Pharmacy Medical Jurisprudence and Hygiene. Pathology. Final Examination Medicine Surgery and Midwifery. Candidates must enter for and pass at the same time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate times but the Final Examination cannot be completed until a period of three years has elapsed from the date of passing Primary Examination Part II.

Application for other information should be made to the Registrar 95 Merrion Square, Dublin.

MEDICAL SCHOOLS AND COLLEGES

LONDON

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

CHARING CROSS HOSPITAL

THIS school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, and for research work. An Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology and bacteriology here, and are encouraged to undertake research.

A number of scholarships and exhibitions are awarded to university and other students, particulars of which can be obtained from the Dean.

Fees—The fees are as follows. Entrance Primary and Intermediate 10 guineas, Final 8 guineas. Annual 38 guineas. Further information may be obtained on application to the Dean of the Medical School Charing Cross Hospital London WC2.

GUY'S HOSPITAL

THE hospital contains 642 beds in constant occupation. Twenty-six beds are set apart for diseases of the eye, and 43 for the most urgent and interesting medical cases, which

form the subjects of the weekly clinical lectures. There are special wards of 47 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system and the children's department, there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs' Union. The athletic ground at Honor Oak Park is reached from the hospital in fifteen minutes. The Gordon Museum of Pathology, the Wills Library, the departments of chemistry, physics, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for all medical degrees and diplomas. New departments of anatomy, physics, and biology have recently been completed. They are equipped on modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second Examinations for medical degrees of the University of London, for the Pre-Medical Examination, and for the First and Final F.R.C.S. Eng. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, four ophthalmic house-surgeons, two genito-urinary house-surgeons, two house-physicians (children's department), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, fractures, and genito-urinary and venereal disease, clinical assistantships in the various special departments are open to post-graduates.

Scholarships, Prizes, etc.—The following scholarships in Arts and Science are awarded: A. Open Junior Scholarships (1) An Arts Scholarship of the value of £100 (2) a Science Scholarship of the value of £100, these are awarded annually in June or July. (3) A War Memorial Scholarship of the value of £200 awarded alternately in Arts and Science. This scholarship is open every other year, the next award will be made in June or July, 1930 (in Science). B. Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually in June or July to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 20 years of age on August 1st of the year of the competition. C. Open Senior Science Scholarships (1) A War Memorial Scholarship of the value of £100 (2) an Open Scholarship of the value of £80 both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency £20 £15 £10 Hilton Prize for Dissection £5 Michael Harris Prize for Anatomy £10 Sands-Cox Scholarship for Physiology £15 for three years. Wooldridge Memorial Prize for Physiology £10 Beaneey Prize for Pathology £34 Treasurer's Gold Medal in Medicine, Treasurer's Gold Medal in Surgery and the Golding Bird Gold Medal and Scholarship for Bacteriology (£20) are awarded annually after competitive examination. The Gull Studentship in Pathology of the value of £250 per annum the Beaneey Scholarship in Materia Medica of the annual value of about £50 and the Andersou Demonstratorship in Clinical Chemistry value £150 per annum are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum and the Hilda and Ronald Poulton Fellowship value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Gny's Hospital, London Bridge, S E 1.

KING'S COLLEGE HOSPITAL

The medical school of this hospital, which is situated at Denmark Hill, deals with the Final Examination subjects of the medical curriculum. The hospital was opened in 1913, and is one of the most modern and best equipped in England. The number of attendances in the casualty and out-patient departments during the year 1927 amounted to 281,620. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physical treatment. The laboratory and pathological department are specially noteworthy.

Appointments.—Sixteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Scholarships, etc.—At entrance Science Scholarship £50. At commencement of Final Studies Anatomy and Physiology Scholarship £50 Pathology Scholarship, £75 two Raymond Gooch Scholarships each £60 a year for two years (two Burney Yeo Scholarships each £80 (for Oxford and Cambridge students), Epson College Scholarship, £50 Senior Scholarship £40 Todd Prize Tanner Prize Class Prizes and Medals.

Fees.—The composition fee is 93 guineas if paid in one sum. Entrance fee of 15 guineas includes membership of the Clubs and Societies Union.

New Dental School.—This school was opened in October, 1923, and provides complete courses for dental degrees and diplomas. The director of dental studies is Dr A. Livingston, M.B., Ch.B., M.D.S., L.D.S.

The calendar of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., F.R.C.S., or to the Secretary of the Medical School, S. C. Ranner, M.A., King's College Hospital, Denmark Hill S E 5.

THE LONDON HOSPITAL

This hospital, with its medical college and dental school, is situated in the Mile End Road, E 1. The hospital contains 837 beds, which are in constant use. During 1927, 16,840 patients passed through the wards and 114,509 out-patients received treatment. Of the latter number, 41,400 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the pediatric, orthopaedic, venereal, radiological, electro- and physico-therapeutic, and inoculation departments. The number of major operations which were performed amounted to 7,823.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time director, assisted by an assistant director, two assistants, and two house-physicians, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of obstetrics and gynaecology there are two assistants and two resident accoucheurs. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. Two resident hostels are provided for the convenience of students. Recent additions to hospital and college buildings include the Dunn Clinical Laboratories, the Barts Clinical Theatre, the Bernikoff Baron Pathological Institute, and a hostel for resident medical officers providing accommodation for forty residents. The athletic ground, of over thirteen acres, is at Higham's Park, and is open to all members of the Clubs Union.

Appointments.—The salaried appointments open to past students of the hospital are those of assistants to the medical unit, first assistants to the medical and surgical firms, obstetric registrar, assistants to the department of obstetrics and gynaecology, medical, surgical, and obstetric tutors, clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Pathological Institute. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians and 22 resident house-surgeons, 14 resident receiving room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes.—The following is a list of scholarships and prizes.—At Entrance: Price Scholarship in Science, £100. Scholarships open to students of Oxford and Cambridge Universities: (1) £75 Anatomy and Physiology, (2) £100 Pathology. Entrance Scholarship in Science, £50. Epsom Scholarship, Free Medical Education. After Entrance: Buxton Prize in Anatomy and Physiology, £40. Letheby Prizes in Organic Chemistry and Chemical Pathology, £25. Prizes in Clinical Medicine, Surgery and Obstetrics and Gynaecology, £20 each. Duckworth Nelson Prize in Practical Medicine and Surgery, £10. Hatchinson Prize in Clinical Surgery, £60. Treves Prize in Clinical Surgery, £15. Sutton Prize in Pathology, £20. K. E. D. Payne Research Scholarship in Pathology, £20. Sir Andrew Clark Prize in Clinical Medicine and Pathology, £14. T. A. M. Ross (prox. acc.) Prize in Clinical Medicine and Pathology, £10. 10s. Anderson Prizes in Elementary Clinical Medicine, £20. Dressers Prizes, £20. Practical Anatomy Prizes, £10. Arnold Thompson Prize in Medical and Surgical Diseases of Children, £15. Liddle Prize, £120. Francis Farmer Scholarship in Dental Surgery, £25. Harold Fink Prize in Dental Surgery, £8 8s. The London Prizes in Dental Surgery and Pathology, £5 5s. and in Dental Prosthetics, £5 5s. Seven class examination prizes each of the value of £3 3s. are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £90,000 permit of financial assistance being given to students and graduates engaged in medical research.

Fees.—Entrance fee 20 or 15 guineas, according to examinations passed; annual fee 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

THE MIDDLESEX HOSPITAL

The school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goodge Street, and Great Portland Street stations. There are a gymnasium, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for mental cases for cases of venereal disease, and for diseases of children and of the skin and eye.

The medical school, which includes the Bland-Sutton Institute of Pathology, the S. A. Courtauld Institute of Biochemistry, and the cancer research laboratories, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute under the charge of the Professor of Pathology contains large pathological and public health laboratories, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried

out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The Biochemical Institute is under the charge of the Professor of Biochemistry, and contains teaching and research laboratories in addition to those devoted to the routine clinical work of the hospital. The cancer research laboratories offer unrivalled opportunities for the study of this disease, in both its clinical and pathological aspects.

Appointments.—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination, six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. Nine registrars are appointed annually. In the out-patient departments the appointments are clerk and dresser to the physicians and surgeons to out-patients, clerk in the departments for diseases of the skin and nervous diseases, dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's, and electro-therapeutic out-patient departments.

Scholarships.—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships of the value of £90 and £60 respectively are open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in anatomy and physiology. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £90 and £40. Lyell Gold Medal and Scholarship, value £55 5s. Freeman Scholarship, value £30. John Murray Gold Medal and Scholarship, value £25. Hetley Clinical Prize, value £25. Leopold Hudson Prize, value 11 guineas, and the Second Year's Exhibition, value 10 guineas.

The rebuilding of the hospital is being carried out without the loss of a single bed, or any disorganization of its clinics.

Fees.—(a) Pre-medical students. For one year or less, £21. (b) Students who have completed the Preliminary Science course. Entrance fee 25 guineas, payable on joining the medical school, five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. (c) Oxford and Cambridge and other students who have completed the Intermediate course. Entrance fee 15 guineas, three annual fees of £45, further annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination, fevers, etc. and also the subscription to the amalgamated clubs and hospital journal.

Further information may be obtained from the Dean or the School Secretary.

ST BARTHOLOMEW'S HOSPITAL

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings, it is on the edge of the City and easily reached from all parts of London. The hospital contains 757 beds. Extensive buildings opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient depart-

ment and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive *post-mortem* room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was acquired in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology. A new block of surgical wards and operation theatres is in course of construction. The Students' Union owns grounds of some ten acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch. Oxon., M.Chir. Cantab., M.S. Lond., and F.R.C.S. Eng.

Clinical Units—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director, who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers are open to all students in these departments, and arrangements are made for all students to study in these units during a part of their clinical course.

Appointments—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological, children's, laryngological, aural dermatological, venereal, electrical, and dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men, appointed yearly to help in the general medical, surgical, and in special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships—Four Entrance Scholarships are annually awarded after examinations held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship value £75, in not fewer than two and not more than three of the following subjects: chemistry, physics, botany, zoology, physiology, pathology and anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship value £100 in not fewer than three of the following subjects: chemistry, physics, botany, zoology, and physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) An entrance scholarship in arts, of the value of £100 in mathematics, Latin or Greek or French or German, a second language or chemistry or physics. (4) The Jefferson Exhibition in the same subjects as No. 3—of the value of £50. Candidates for Nos. 3 and 4 must be under 19 years of age. The total value of the scholarships and prizes is over £1,200 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital E.C.1.

ST GEORGE'S HOSPITAL

THIS school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centre of London University established at King's College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

Appointments—Two house-physicians, two house-surgeons, and two casualty officers are appointed every two months. The house officers reside and board in the hospital free of expense. The casualty officers are non-resident, and receive salaries at the rate of £100 per annum. After the student has held a house appointment, the following are, among others, open to him: assistant resident physician at £350 per annum, assistant resident surgeon at £350 per annum, medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum, medical registrarship at £200 per annum, surgical registrarship at £200 per annum, medical officer to the biochemical department at £100 per annum, assistant curatorship of the museum, £100 per annum, obstetric assistantship, resident, at £50 per annum, the post of resident anaesthetist at £100 per annum, the posts (three) of junior anaesthetist, each at £30 per annum.

Scholarships—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B. London or corresponding examination. Senior William Brown Exhibition of the value of £120, Senior Scholarship of the value of 90 guineas, Junior William Brown Exhibition of the value of £80, Junior Scholarship of the value of £70, Dentist Pendlebury Scholarship of the value of £50 and Exhibitions each of the value of £40 and up to six in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees—First year (First M.B. or pre-medical course), £36 15s. second and third years £42 each. For the course of clinical study in the fourth and subsequent years entrance fee £10 10s. annual composition fee £42. No entrance fee is payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

ST MARY'S HOSPITAL

THIS hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 348 beds, and extensions recently completed have provided two new operating theatres. By a scheme of affiliation, for teaching purposes, of several neighbouring hospitals, the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the courses of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Wembley, and can be reached in twenty minutes by a constant service of trains.

Clinical Facilities—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee. St. Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the lying-in beds at St. Mary's, every student attends a short course at Queen Charlotte's Maternity Hospital (which is situated near to St. Mary's) before holding a post on the maternity district of the hospital.

Institute of Pathology and Research—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal

direction of Sir Almoth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute, and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the medical school, including ten salaried posts, with salaries varying from £200 to £750 per annum.

Complete Curriculum—The medical school provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships—Two Entrance Scholarships of £210 each and one of £26 5s are awarded annually in July by nomination on the lines of the Rhodes Scholarships. The Geraldine Harnsworth Scholarship (£200) and one or more University Scholarships of £200 are awarded annually in July.

Fees—Composition fees for entire curriculum (6 years) £200 in one sum or £210 by five annual instalments. Composition fee for clinical curriculum (3 years), 90 guineas in one sum or 95 guineas by two annual instalments. As an alternative students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

ST THOMAS'S HOSPITAL

This school and hospital are situated in Lambeth, on the south bank of the Thames facing the Houses of Parliament, and form one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. St Thomas's House, the new Students' Club recently opened, comprises spacious dining and club rooms, etc., and provides accommodation for some sixty resident students. The terrace affords facilities for exercise and recreation. The sports ground, more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital, it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room, it is arranged also for lantern demonstrations. A clinical unit in medicine has been established. The maternity ward, containing 21 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments—All hospital appointments are open to students without charge. A resident assistant physician, a resident assistant surgeon, and a resident anaesthetist are appointed annually at a salary of £200 each per annum. Two hospital registrars, medical and surgical, at an annual salary of £250 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. A pathological registrar to the department of bacteriology and gynaecology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £50), and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Seven house-physicians (including two obstetric house-physicians and

two house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose, and throat department) are appointed every six months. Thirty-six or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships—There are five Entrance Scholarships: two in arts, giving one year's free tuition one of £150 and one of £60 in chemistry, physics, and biology for students who have not received instruction in anatomy or physiology, one of £100 in any two of the following subjects: anatomy, physiology, chemistry or pathology for students who have completed their examinations in anatomy and physiology for a medical degree in any of the universities of the United Kingdom or the Colonies and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second year students, £25; (b) and (c) Musgrave Scholarship or (alternately) Peacock Scholarship, each for third year students and tenable for two years £35 each; (d) Mead Medal, Medicine, Pathology and Hygiene; (e) Wainwright Prize, Medicine; (f) Toller Prize, Medicine; (g) Cheselden Medal, Surgery and Anatomy; (h) Clutton Memorial Medal in Clinical Surgery, biennially; (i) Beaneby Scholarship £50 biennially, Surgery and Surgical Pathology; (j) Solly Medal and Prize biennially, Reports of Cases; (k) Sutton Sams Prize biennially, Reports of Cases; (l) Bristowe Medal, Pathology and Morbid Anatomy; (m) Hadden Prize, Pathology and Morbid Anatomy; (n) Grainger Testimonial Prize £31 10s., Anatomy and Physiology; (o) Louis Jenner Research Scholarship, tenable for two years £60 annually, Pathology; (p) School Council Research Scholarship, £250 per annum; (q) John and Temple Research Scholarship, value £450 per annum (children).

Fees—The annual fees are: For each year of study £50. These fees cover all tutorial classes but do not include instruction in infectious fever, pharmacy and vaccination. A limited number of qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Special courses of instruction are given for various examinations and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School, St Thomas's Hospital, Albert Embankment, S.E.1.

UNIVERSITY COLLEGE HOSPITAL

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine, surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The hospital and school have acquired the National Dental Hospital and College as their dental departments, thus providing every facility for the study of dental subjects. The Royal Ear Hospital has also been amalgamated as the Ear, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital is completed.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and in Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas in public health. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine, surgery, and obstetric medicine are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital.

The new buildings of the obstetric hospital of 74 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 33 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation.

Appointments—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrars, surgical registrar, obstetric registrar, Barker Smith radium registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

Scholarships—The following scholarships and prizes are open to competition. Two Entrance Exhibitions of 112 guineas each, awarded after a competitive examination in any two of the following subjects: Anatomy, Physiology, or General Pathology, Radcliffe Crocker Travelling Scholarship in dermatology for one year value about £280, the Graham Scholarship in pathology of a sum not exceeding £400 per annum, Leslie Pearce Gould Research Scholarship in surgery for one year, value about £200, the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery, the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies, the Magrath Clinical Scholarship, value about £150, the Filsher Exhibition in pathology of £30, the Percival Allyn Prize for the advancement of surgery by research value about £75, the Graham Gold Medal for research work four Fellows Medals in clinical medicine, Luston Medals in clinical surgery, the Bruce Medal in pathology and surgery, two Tuko Medals in pathology, and the Erichsen Prize for practical surgery.

Fees—The fee for the full course of final studies at the school is 112 guineas if paid in one sum, or 115 guineas if paid in two instalments. Fees for vaccination, fevers, and pharmacy not included.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street W.C.1.

WESTMINSTER HOSPITAL

This school, with its hospital, situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,500 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

Appointments—A medical and surgical registrar are appointed annually, each with a salary of £150, and an obstetric registrar with a salary of £50. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. Two house-anaesthetists are appointed for three months, non-resident, salary £50 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duties of out-patient dresser for three months, and afterwards hold the office of in-patient dresser for three months. He is also required to serve two terms of three months each as medical clinical clerk to the in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

The governors of the hospital have now completed the extensive improvements and alterations to the hospital, which render it a still more efficient teaching institution, with an increased number of beds.

The athletic ground is situated at Tooting, and can be reached in twenty minutes from the hospital.

Scholarships—The following open scholarships are offered for competition during the year 1928-29. In the winter session two scholarships in anatomy and physiology, £75 each. In the spring two scholarships in anatomy and physiology, £75 each. A certain number of scholarships have been allotted to universities of England, Wales, and the Colonies and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the university or school.

Fees—The annual composition fee is £40. An entrance fee of 10 guineas is payable by all students—namely primary and intermediate students £10 10s, students entering for the final subjects, £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital Westminster S.W.1.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union room, and refectory are provided for the use of students. Resident accommodation for 78 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 268 beds, all of which are available for clinical instruction. A new block contains the obstetrical and gynaecological unit, which controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, children and infant welfare, venereal diseases, orthopaedic surgery, massage, light, electrical and x-ray work, dentistry, and casualty. The instruction given covers the full curriculum for the M.B., B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Bethlem Hospital, they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the Medical School and general hospital course for dental students.

Appointments—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships—The Isabel Thorne Entrance Scholarship value £30, the St Dunstan's Medical Exhibition, value £60 a year for three years which may be extended to five years, the Alfred Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50 and the Mahel Sharmar-Crawford Scholarship value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs George M. Smith Scholarship of the value of £50 a year for three years which may be extended to five years, the Dr Margaret Todd Scholarship of the value of £37 10s a year for four years, and the Sarah Holborn Scholarship of the value of £20 a year for three years which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Bostock Scholarship value £30 a year for two or four years is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship of the value of £25 a year for four years is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Julia Ann Hornblower Cock Price of £60, the Helen Pridaux Prize of £60, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Rider

Scholarship of £16 a year for four years together with many other scholarships and prizes are offered on sundry conditions. The Dr Edith Peechey Plimpton Post Graduate Scholarship of £100 is awarded annually. Altogether the school offers annually £1 350 in scholarships. Various missionary societies also offer scholarships on certain conditions and assist women who wish to go to India and other countries as medical missionaries.

Fees—Courses for the University of London degrees and the diplomas of the Conjoint Board in England and other qualifications £240 payable in five instalments. These sums include library and laboratory fees.

The Students Union exists to promote corporate action of the students on matters of common interest to promote and maintain athletic and other clubs and to issue a school magazine. All students are required to become members of the Union. The students sports ground which consists of a freehold property of seven and a half acres is situated at Sudbury.

Further information can be obtained from the Warden and Secretary.

KING'S COLLEGE

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, including the primary examination for the F.R.C.S. Eng. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to a hospital to pursue their studies for the final examinations. The hospitals associated with King's College are King's College Hospital, Denmark Hill, S.E.5, Westminster Hospital, S.W.1, St George's Hospital, Hyde Park Corner, S.W.1, and Charing Cross Hospital, Strand, W.C.2.

A course for the degree of the University of London and for the Diploma of the Royal College of Surgeons in dental surgery in conjunction with King's College Hospital Medical School has been arranged.

Scholarships—The entrance scholarships are (1) Two Warneford Scholarships each £30 for four years subjects—selected from mathematics, classics, divinity and science. (2) One Sambrook Scholarship of £30 for three years subjects of examination selected from mathematics, classics and science. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100 paid in five annual instalments. (4) Rabbeth Scholarships, value £30 and £15, in July for the best student of the first year. (5) Second year's scholarship, value £20, for the best student of the second year. (6) Daniell Scholarship, £30 awarded on the results of the University Honours Examination. (7) The Layton and Berridge Studentships each £150 per annum and (8) numerous prizes.

Full information as to admission fees and scholarships can be obtained from the Dean of the Faculty of Medical Science, King's College, Strand, W.C.2.

UNIVERSITY COLLEGE

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology, and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. The department of hygiene and public health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society,

or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Faling, and for about seventy women students at Byng Place, Gordon Square.

Scholarships—The scholarships and exhibitions obtainable include the Bucknill Scholarship value 160 guineas in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), two entrance exhibitions in the same subjects each of the value of 55 guineas, and a Faculty of Medical Sciences Entrance Scholarship value £30 a year for three years.

Fees—The fees for the courses covering the work of the First Examination for medical degrees of the University of London and in both parts of the Second Examination amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses which it may be desired to take out but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London W.C.1.

THE PROVINCES

There are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases information is appended about hospitals other than those directly connected with the school in question. Such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

OXFORD AND CAMBRIDGE

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done, and is never in the ordinary way advised by the university medical authorities. The local hospitals—the Radcliffe Infirmary at Oxford, and Addenbrooke's Hospital at Cambridge—though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join one of the London medical schools, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is a naturally of much advantage when sitting for the Final M.B. examination and when engaged in composing a thesis.

BIRMINGHAM

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for the purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, with an array of special departments of all kinds, including one for living-in women. Clinical instruction is given in the wards and out-patient and special departments daily and formal clinical lectures are delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

Appointments—The large number of appointments open to past or other students includes the following.—At the General Hospital: surgical registrar, £200 a year, one resident medical officer, salary £155 a year, one resident surgical officer, salary £180 a year, one assistant resident

surgical officer, salary £100 a year, one resident pathologist, salary £70 a year, two visiting anaesthetists, salary £50 a year, one resident anaesthetist, salary £70 a year, four house-surgeons, office tenable for nine months, £70 a year, one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year, four house-physicians, post tenable for six months, £70 a year. At the Queen's Hospital one medical registrar and one surgical registrar, non-resident, tenable for three years, renewable, salary £100 per annum, three house-physicians, three house-surgeons, and one obstetric and ophthalmic house-surgeon, tenable for six months, salary £70 per annum, with board, lodging, and washing, one casualty house-surgeon, tenable for three months, salary £70 per annum, with board, lodging, and washing. At the Maternity Hospital three house-surgeons, salary £50 a year. At the City Workhouse and Workhouse Infirmary five resident medical officers. At the Birmingham General and Branch Dispensaries twelve resident surgeons. At the Birmingham Mental Hospitals five assistant medical officers. At the City Fever Hospitals three assistant medical officers. At the Children's Hospital one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital four resident surgeons. At the Orthopaedic and Spinal Hospital two clinical assistants (non-resident). At the Ear and Throat Hospital one house-surgeon, £70 a year, four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

Scholarships—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £300 offered each alternate year for research work and tenable abroad, the Sands Cox Scholarship of £42 (an entrance scholarship to the Faculty of Medicine awarded on Higher School Certificate Examination of the Joint Matriculation Board (July)), four Queen's Scholarships of £10 10s each, awarded annually at the first (Part II) second, third and final university examinations respectively, one or more Sydenham Scholarships allotted on entrance to students who are the sons of deceased medical men, the Ingleby Scholarships (two) of £10 for proficiency in midwifery and diseases of women, the Arthur Foxwell Memorial Gold Medal (Clinical Medicine), the Sampson Gamgee Memorial Medal for Surgery (Final M.B.), and the Peter Thompson Prize in Anatomy (value about £6) for students in their second university year. There is also a scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize Gold Medal, Senior Surgical Prize Gold Medal, Midwifery Prize Gold Medal, Junior Medical Prize Silver Medal, Junior Surgical Prize Silver Medal.

Fees—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities and for the ordinary qualifications of licensing corporations but not the additional courses required for the Fellowship of the Royal College of Surgeons of England the diploma and degrees of the university in State medicine, and some other special work. The total cost for the five years' curriculum including hospital and examination fees is estimated at £221 4s. 6d. Other information should be sought from the Dean of the Medical Faculty, University Edmund Street Birmingham.

BRISTOL

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and for the diploma in dental surgery.

Clinical Instruction—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them 628 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to large and well-equipped departments for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work, both for diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finson light treatment, and massage. The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 100 beds, and that of the Bristol Eye Hospital, with 40 beds. In addition, by the kind permission of the Bristol Board of Guardians, students may attend the

clinical practice at Southmead Hospital, which has 556 beds. The total number of beds available for clinical instruction is therefore 1,324.

Appointments—(1) Undergraduate Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate. At the Bristol Royal Infirmary four house-surgeons, one casualty house-surgeon, two house-physicians, one house-physician for cancer research wards, one resident obstetric officer, one ophthalmic and gynaecological house-surgeon, one ear, nose, and throat house-surgeon, one assistant to the senior resident medical officer, who also acts as house-surgeon and house-surgeon to the skin department, and one dental house-surgeon. All these appointments are for six months. Salary in each case at the rate of £80 per annum, with board, apartments, and laundry, unless the candidate appointed has previously held a resident appointment in the infirmary, when the salary will be at the rate of £100 per annum, with board, apartments, and laundry. From the resident medical officers a senior resident medical officer is appointed at a salary of £200 per annum. At the Bristol General Hospital senior resident medical officer, £250 per annum, casualty house-surgeon, £80 per annum, two house-physicians, £80 per annum, house-surgeon, £80 per annum, resident obstetric officer, £80 per annum, house-surgeon to special departments, £80 per annum, dental house-surgeon (non-resident), £300 per annum. The appointment of resident anaesthetist is also being created. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship value £40 open to women only two Martin Memorial Pathological Scholarships of £30 each the Tibbitts Memorial Prize, value 7 guineas for proficiency in practical surgery the Committee's Gold and Silver Medals for fifth-year students for general proficiency, the Augustin Prechard Prize, value about 6 guineas for proficiency in anatomy the Henry Clark Prize value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize value 6 guineas, for proficiency in surgery the Supple Surgical Prize a gold medal and 7 guineas the Supple Medical Prize a gold medal and 7 guineas the Henry Marshall Prize value £12, for dressers, the H. M. Clarke Scholarship, value £15 for proficiency in surgery the Sanders Scholarship, value £22 10s. for general proficiency, the Barrett-Routé Scholarship for proficiency in diseases of the nose, throat, and ear or skin value £17 Lady Habersfield Scholarship, value about 25 guineas, Phyllis Stepmar Prize for proficiency in diseases of children, value £25 Bristol City Senior Scholarships and the Senior Scholarships offered by the counties of Gloucestershire Somerset Wilts Devon etc., are tenable to the university. Some of the Fellowships awarded by the Colston Research Society for research in the university are allotted to the Faculty of Medicine.

Fees—The fee for all the courses required for the medical curriculum including hospital practice, is 205 guineas paid by annual instalments.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

This, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, New castle-upon-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university; Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, where there are facilities for the study of the various special subjects. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, is thoroughly up to date, and has an annual indoor and outdoor attendance on 3,000 cases. In a Heath wing of the school itself there is the department of physiology. There are also in this wing a gymnasium and a set of rooms for the separate use of the students. A new bacteriological department has been erected adjacent to Armstrong College.

Post-Graduate Instruction—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College,

the Royal Victoria Infirmary, and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

Students' Union—A Students' Union has been erected and furnished at a cost of over £40,000, and is in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments—Pathological assistants, and assistants in the oyo department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

Scholarships—University of Durham Entrance Scholarship £25 a year for four years. Pears Entrance Scholarship £40 a year for three years (awarded every third year). Heath Entrance Scholarship (from Kipper Grammar School), £60 (renewable). Province of Durham Ansonic (Entrance) Scholarship, £60 (renewable). Heath Scholarship for surgery £200 available every second year. Rutherford Morrison Surgical Scholarship, £180, available every third year.

The following scholarships are tenable for one year—namely, Tulloch Scholarship for elementary biology and organic chemistry, £20. Dickinson Scholarship for medicine surgery, midwifery and pathology. Gold Medal and £20. Charlton Scholarship for medicine, £25. Gibb Scholarship for pathology £28. Luke Armstrong Scholarship for comparative pathology £25. Stephen Scott Scholarship for surgery, £40. Philipson Scholarships for highest marks in Final M.B. B.S. Examination, two of £48 each. Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325. Gibson Prize for midwifery and diseases of women and children £10. Turnbull Prize and Silver Medal for surface anatomy. Outtersen Wood Prize for psychological medicine £10, and Sewell Memorial Prize and Silver Medal for clinical pathology. At the end of each session a prize of books is awarded in each of the regular classes.

Fees—The composition fee for lectures at the college is £140. Composition fee for hospital practice, £46 plus £2 2s yearly for three years payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Dean of the College. University of Durham College of Medicine Newcastle-upon-Tyne.

LEEDS

The School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, well arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, a special children's ward, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, have 88 beds. The West Riding Mental Hospital at Wakefield is open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital, where the obstetric work is done.

Appointments—Surgical dressers are appointed every six months, physicians' clerks, clerks in the children's department, orthopaedic dressers, ophthalmic and anal dressers, gynaecological ward clerks, maternity clerks, assistant physicians' clerk, dermatological clerks, assistant surgeons dressers, dressers in the casualty room, *post-mortem* clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation a considerable number of residential and other appointments become available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university which are covered by the composition fee. The university also awards a scholarship on the results of the first

examination of the value of £68, in the form of a free admission to the clinical teaching of the infirmary.

Fees—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £324, plus of course, the expenses of living during the five and a half years covered by the curriculum. The composition fee for the course for the first second and third examinations, and for the clinical work at the infirmary is £237. The composition and clinical fee for those who have passed the second examination is £150.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine Leeds.

LIVERPOOL

The Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which a list is given below, have amalgamated to form the clinical school of the university.

Appointments—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships—The awards made each year to successful students total over £1,500. They include the following: Two Holt Fellowships, one in Pathology the other in Physiology, a Robert Gee Fellowship in Anatomy, two John Rankin Fellowships in Anatomy, a John W. Garrett International Fellowship in Bacteriology, a Johnston Colonial Fellowship in Biochemistry, an Ethel Boyce Fellowship in Gynaecology, and a Thelwall Thomas Fellowship in Surgical Pathology, one Lady Jones Fellowship in Orthopaedic Surgery (value of fellowships: one at £200, three at £150, two at £120, four at £100). A University Scholarship of £50 awarded on the results of the Final M.B. (Part A) Examinations, a Scholarship in Mechanical Dentistry of £20, two Lyon Jones Scholarships of the annual value of £21 each for two years, one for the junior and the other for the senior students, the Derby Exhibition of £15, the Clinical School Exhibition of £15, the Owen T. Williams Prize, the Torr Gold Medal in Anatomy, John Rankin Exhibition in Practical Anatomy £25, the George Holt Medal in Physiology, the Kantback Medal in Pathology, Mitchell Banks Medal in Anatomy, the Robert Gee Prize of £5 5s in Children's Diseases, Mary Birrell Davies Memorial Scholarship (women) £60 per annum for four years, Robert Gee Entrance Scholarship (men) value of £42 10s per annum for four years, Dental Operating Prizes (four), Orthodontia Prizes (two), Samuels Memorial Scholarships three at £20 each, one Thomas H. Bickerton Prize in Anatomy, Dr N. E. Robert Prize in Zymotic Diseases, Asha Prize in Dental Surgery, value £2 2s, Gilmour Medal and other entrance scholarships. In addition a number of gold and silver medals have recently been instituted in the following subjects: Pharmacology, Surgery, Forensic Medicine and Toxicology, Public Health, Medicine, Obstetrics and Gynaecology, Orthopaedic Surgery and Laryngology and Otolaryngology.

Fees—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School

As many as nine hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women (with the Samaritan Hospital), the Liverpool Maternity Hospital, the Eve and Ear Infirmary, and St. Paul's Eye Hospital. Between them they provide over 1,445 beds.

MANCHESTER

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains 614 beds, and has associated with it a large convalescent home (132 beds) and a Central Branch Hospital (54 beds). The courses in mental diseases are partly taken in the County Mental Hospitals at Prestwich and Macclesfield. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition. Two surgical registrars, at £150 per annum, two pathological registrars, at £100 and £50 per annum, one medical registrar, at £150 per annum, a cardiographic registrar, at £150 per annum, a surgical tutor, at £30 per annum, a director of the clinical laboratory, at £400 per annum, and two assistants, at £350 and £300, three assistant medical officers and three assistant surgical officers, each at £35 per annum, assistant surgical officers, aural department, at £35 per annum, seven anaesthetists, from £75 to £125 per annum each, one resident medical officer, one year, £200 per annum, one resident surgical officer, one year, £200 per annum, three resident medical officers for Central Branch, one at £200 and two at £100 per annum, one assistant resident surgical officer, £150 per annum, one resident medical officer at the Convalescent Hospital at Cheadle, £250 per annum, two assistant medical officers to radiological department, £150 and £105 per annum, medical officer, physio-therapeutic department, £150 per annum, assistant surgical officer, gynaecological department, £35 per annum, assistant to the dermatologist, £20 per annum, and three assistant surgical officers for Central Branch, £75 per annum, ten senior and ten junior house-surgeons and ten house-physicians, appointed during the year for periods of six months, at a salary of £50 for the first six months, and £100 for the second six months. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical women, tenable for six months, at an honorarium of £35.

Entrance and other Scholarships—The following are among the scholarships obtainable by students of the school. Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum tenable for two years. Three Hulme Scholarships tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35 tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dora Muir Scholarship, £30 per annum tenable for three years and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum tenable for three years, awarded triennially open to the competition of scholars from Sedburgh School, Giggleswick School and Burnley Grammar School subjects—mathematics, chemistry, and mechanics. Drieschfeld Memorial Scholarship value £20 tenable for two years and awarded triennially on the result of the Entrance Examination. John Russell Medical Entrance Scholarship, awarded annually value £45. Two Dauntsey Junior Medical Scholarships value £50 each tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification subjects—zoology, botany and chemistry. One Dauntsey Senior Medical Scholarship £50 for one year awarded on results of Second M.B. Examination. Two Entrance Scholarships in Medicine value 100 guineas, awarded annually for proficiency in arts or science respectively. Tom Jones Exhibition in Anatomy £25 offered annually. A Robert Platt Physiological Scholarship of £30 tenable for one year. A Leech Fellowship of £100 for original research after graduation. Graduate Prize in Medicine £5 annually. A Graduate Research Scholarship in Medicine value £70 tenable for one year awarded annually for proficiency shown at Final M.B. Examination, open to Graduate Prizemen. A Dumville Surgical Prize value £15 awarded annually at graduation. The Tom Jones Memorial Surgical Fellowship value £105 tenable for one year, usually awarded annually. The Turner Medical Prize value £20 awarded annually for proficiency in certain subjects of the Final M.B. Ch.B. Examination. The John Henry Agnew Prize of £30 awarded annually for proficiency in the Diseases of Children. The Asby Memorial Scholarship tenable for one year (£100), for research in the Diseases of Children, offered triennially. Sidney Renshaw Prize in Physiology one offered annually (£15). Wild Prize in Pharmacology. The John Henry Agnew Fellowship in Diseases of Children £120, offered triennially. Eliza Warple Holt Post Graduate Medical Scholarship for Women £60 for one year offered biennially. The details and regulations of the Dickinson Scholarships—(1) for Anatomy, (2) for Pathology, (3) Research Scholarship in Surgery and (4) Traveling Scholarship in Medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in Anatomy is offered annually value £150. Also the Sheridan Delapine Fellowship in Preventive Medicine value £300 is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum tenable for not more than four years to women students who have passed the First M.B. Examination, the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or

medical practitioners who have been registered in the university as candidates for that diploma.

Fees—The composition fee for the university course in medicine is 110 guineas, payable in four instalments of 27½ guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one sum. Hospital fees are additional, and usually amount to about 77 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

Clinical Work—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury, and St Mary's Hospitals for Women and Children, the Manchester Hospital for Diseases of the Ear, Monsall Fever Hospital, the Christie Cancer Hospital, the Hospital for Consumption and Diseases of the Throat and Chest, the Ancoats Hospital, and the Salford Royal Hospital, all make arrangements for the instruction of students.

SHEFFIELD

In this city the medical school is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. There are also two student unions—one for men and one for women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at other institution by the anaesthetists, and the *post mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Mental Hospital.

Appointments—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships—Entrance Medical Scholarship value about £190 open to both sexes. Sir Edgar Allen Scholarships of £125 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees Scholarships each of the value of £50 tenable for three years for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees Scholarships value £50 for

boys or girls under 19 years of age educated in any school in Sheffield, secondary or otherwise. Town Trustees Fellowship, value £75, tenable for one year. Mechanics Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50 tenable for two years. Kaye Scholarship for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £38 for each of the five years. The composition fees for the dental courses are as follows: for B.D.S. first and third years £75, second fourth and fifth years £25 for L.D.S. first and second years £75, third and fourth years £25. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

THE WELSH NATIONAL SCHOOL OF MEDICINE

The next session opens on October 2nd. All classes are open to both men and women students. Particulars relating to the admission of students as from October 1st, 1928, can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport Road, Cardiff.

The following is a list of heads of departments: Physics, Professor H. R. Robinson, Chemistry, Professor W. J. Jones, Zoology, Professor W. M. Tattersall, Botany, Professor R. C. McLean, Anatomy, Professor C. McLaren West, Physiology, Professor T. Graham Brown, Materia Medica and Pharmacology, Dr. W. Mitchell Stevens, Pathology and Bacteriology, Professor J. H. Dible, Medicine, Professor A. H. Kennedy, Surgery, Professor A. W. Sheen, Obstetrics and Gynaecology, Sir Ewen J. Maclean, Preventive Medicine, Professor Edgar L. Collis, Tuberculosis, Professor S. Lyle Cummins.

SCOTLAND

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for post-graduation work.

ABERDEEN

The school is conducted by the Faculty of Medicine. This comprises thirteen chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and preparatory), chemistry (ordinary and preparatory), anatomy, physiology, materia medica, pathology, bacteriology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and infectious diseases, tropical medicine, medical ethics, tuberculosis, and clinical methods are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 370 patients), the Royal Mental Hospital (800 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (350 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital, in fevers at the City Fever Hospital, in mental diseases at the Royal Mental Hospital, in diseases of the ear, nose, and throat at the Infirmary and Dispensary, in diseases of the eye at the Infirmary and Eye Institution, in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.). A Diploma in Public Health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty.

Bursaries, scholarships, and fellowships, to the number of fifty and of the annual value of £1,200, may be held by students of medicine in this university. They range from £8 to £150 per annum, and are tenable in most cases for two or three years. The winter session begins on October 9th, 1928, the summer session on April 17th, 1929.

Fees—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B. Ch.B. is 33 guineas. The total cost including hospital fees, class and matriculation fees and degree fees is about £236.

EDINBURGH

There are two Schools of Medicine: the School of the University, and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

THE UNIVERSITY SCHOOL—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum, Zoological Laboratory and Museum of Science and Art, Physical Laboratory, Chemical Laboratories, Dissecting Room, Bone Room, and Anatomical Museum, Physiological Laboratory, Medical Jurisprudence Laboratories, John Usher Institute of Public Health, Materia Medica Museum and Laboratory, *Post-mortem* Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory, Tutorial Classes of Practice of Physics, of Clinical Medicine, and Clinical Surgery, Surgery and Midwifery, and the practice of certain other hospitals.

Fees—The seasonal fee for chemistry, anatomy, lectures, physiology, pathology, materia medica, surgery, medicine, and midwifery is £8 6s each. Physics, botany, zoology, forensic medicine, and public health £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, clinical midwifery and medical entomology and parasitology, £1 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), clinical medicine (per term), and experimental pharmacology £3 3s. Practical anatomy (winter) £6 16s 6d. Practical chemistry £4 14s 6d. Regional anatomy, chemical physiology, surgical pathology, and infectious diseases £1 11s 6d. Tuberculosis, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin and venereal diseases £2 12s 6d. Advanced bacteriology £7 17s 6d. Clinical gynaecology and applied anatomy £2 2s.

Scholarships—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards and the conditions attaching to them are so varied that those interested should consult the prospectus of the school itself. No other university is in a better even if as good position to smooth the financial path of earnest students.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*, for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Surgeons, and five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street, (2) New School, Bristo Street, (3) Nicolson Square, (4) Marshall Street, and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 6d) on application to the Dean of the School, Surgeons' Hall, Edinburgh.

WOMEN STUDENTS IN EDINBURGH—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed. In clinical medicine and clinical surgery, however, while the lectures are attended by mixed classes, the women students are restricted to the wards of one charge. The particular wards are changed every six months, each of the physicians and surgeons to the infirmary taking the women students in rotation. With few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extra-mural classes taught by the lecturers of the School of Medicine of the Royal Colleges. Most of the Students' Societies are open to women, with the exception of the University Union and the Royal Medical Society. Their place is taken by the Women Students' Union and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the university. The membership of the Royal College of Physicians and Fellowships of the two Royal Colleges are also open to women. Information on matters connected with women's studies may be obtained from the Lady Warden, University New Buildings, Edinburgh.

GLASGOW

THE UNIVERSITY SCHOOL FOR MEN—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: Pathology, Public Health, Pharmacology, Physiology, Surgery, Anatomy, Chemistry, Zoology, Physics, and Botany. The Botanic Garden and the Hunterian Museum (Pathology) are also open to students. Well-equipped new buildings have been provided for botany, zoology, practical anatomy, and operative surgery, as well as for pathology, the very large additions made a number of years ago to the chemical laboratory render it one of the most extensive in Scotland. The classrooms and laboratories for the departments of Physics, Physiology, Pharmacology, Materia Medica, Medical Jurisprudence, and Public Health are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established, the professors being specially attached to the Royal Infirmary, and a number of university lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, Psychological Medicine, Tuberculosis, and Electrical Diagnosis and Treatment have been founded there. Other chairs have been founded at the university in Bacteriology, Organic Chemistry, Physiological Chemistry, Applied Physics, Public Health, and Pediatrics. There are also lectureships on the Surgical and Medical Diseases of Children and on Electrical Diagnosis and Therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduation and research work. A Diploma in Public Health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached, the Royal Infirmary (688 beds), and the Victoria Infirmary (380 beds), while the Royal Mental Hospital, Gartnavel (500 beds), the Royal Hospital for Sick Children (275 beds), the Royal Maternity and Women's Hospital (114 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35) beds, the

fever hospitals at Belvidere (680 beds) and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches. The large general hospitals of the parish council are now also available for clinical instruction in medicine and surgery. Information regarding post-graduate study will be found at page 410.

Bursaries—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in arts.

The following bursaries are open to undergraduates of both sexes. The Gibson Bursary, annual value £36, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland, and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. The Arbroath Bursary, annual value £40 tenable for three years, is awarded by the Senate on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates, as shown by their class records and their performances in the First and Second Professional Examinations. One Logan Bursary, annual value £16, tenable for four years appointment by the Senate. Six Lorimer Bursaries (each £20 and tenable for one year) are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. The Macintosh Mental Science Bursary in medicine of the value of £31, is awarded annually to the student (of either sex) attending the class of insanity who stands first in an examination in that subject, the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardner Bursary, annual value £14 tenable for two years will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination and whose aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. Of the eight James A. Paterson Bursaries two are awarded each year, they are of the value of £30 and £20 respectively and are tenable for four years, examination in mathematics and natural philosophy in June for students entering the first and second years of medical study. The following are tenable in any faculty. Four Nicolson Bursaries (each £75 and tenable for four years). Two Pratt Bursaries (each £20 and tenable for four years) and two Taylor Bursaries (each £10 and tenable for four years). Andrew and Bethna Stewart Bursaries (£50 each tenable for three years), candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society's Bursaries for students of Highland descent of the annual value of £25 and tenable for five years two vacant each year.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction under conditions given in the *University Calendar*, and summarized at page 387 of this issue. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Bruntton Memorial Prize of £20 is awarded annually to the most distinguished graduate in medicine of the year and the West of Scotland R.A.M.C. Memorial Prize to the candidate for the degrees of M.B., Ch.B. who obtains the highest aggregate marks in medicine, surgery, and midwifery in the Final Examinations. The University Commissioners have issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships and fellowships. Scholarships and fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study. There are also four McCunn Medical Research Scholarships (two of £200 and two of £400) for graduates in medicine of the Scottish universities, one Faulds Fellowship for Research in Medical Science of approximately £200 for three years, and one Strang Steel Scholarship value £160, for one year. There is, in addition, 'The Captain H. S. Rankin V.C. Memorial Prize in Pathology.

Fees—The matriculation fee for each year is £2 2s. In most cases the fee for each university class is £8 6s. but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s. for a perpetual ticket, or £1 11s. 6d. for a single term ticket with an additional fee of £5 5s. for each winter and £2 12s. 6d. per term for each clinical course. The fees are the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £250.

For further information apply to the Registrar, Glasgow University.

QUEEN MARGARET COLLEGE—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading rooms, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary, also *inter alia* in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal

Asylum, Gartnavel, Halkhead Asylum, the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidero and Ruchill, and the Glasgow Royal Maternity and Women's Hospital

Scholarships—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1928. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Queen Margaret College, Glasgow.

Board for Students—University houses of residence for women students, Queen Margaret Hall and Robertson Hall, are situated near the college. The cost of board and residence is from 32s 6d to 42s a week, according to accommodation. Applications to be made to the Wardens. Another hostel near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board is from 28s to 30s weekly. Applications to be made to the Warden.

St Mungo's College—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has communication with every part of the city. St Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) over 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department in 1926 over 58,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most improved apparatus for diagnosis and treatment.

Appointments—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees—The average class fee is £3 3s for summer classes and £4 4s for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary, pathology in the Western or Royal Infirmary, vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in public health are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

Fees—The fees for the lectures and practical work required by ordinary students range between 2 and 5 guineas a session. In the Public Health Department the fee for a six months course is £14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with 160 beds, offers facilities for clinical instruction in the diseases peculiar to women. A university lectureship, the Royal Samaritan Lectureship in Gynaecology, is associated with the hospital. The lecturer is Dr David Shannon. Particulars may be obtained from Mr T. Mason Macquaker, M.A., Secretary, 149, St Vincent Street, Glasgow.

ST ANDREWS AND DUNDEE

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St Andrews, but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s to £5 12s 6d for systematic classes, and from £4 14s 6d to £4 4s for practical classes. The hospital ticket is £1 8s for three months, £4 4s a year, or perpetual, £13 6s 8d in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given there being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND

THERE is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally wide and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

DUBLIN

School of Physic

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

The Schools of Surgery

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich, they are attached to the college by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes—Among the prizes annually awarded are The Barker Anatomical Prize (£25 5s), the Carmichael Scholarship (£15), the Mayne Scholarship (£8), the Gold Medal in Surgery (the Honorary Memorial Gold Medal in Anatomy the H. Macnaughton Jones Gold Medal for Midwifery and Gynaecology) class prizes accompanied by silver medals will also be given in each subject. At intervals a prize of £150 is awarded called the R. Dancer Purfoy Memorial.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin

This is one of the constituent colleges of the National University of Ireland. The arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for information may be addressed to the Secretary and Bursar, University College, Dublin.

Clinical Work

There are numerous well-arranged hospitals in and around the city and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds, Dr Steevens's Hospital at Kingsbridge, with 150, Meath Hospital and County Dublin Infirmary, with 160, Mercer's Hospital, close to Trinity College, with 120, the Royal City of Dublin Hospital, with 124, the Adelaide Hospital, with 140, the Royal Victoria Eye and Ear Hospital, with 100 beds, St Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwick Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. It receives nearly 3,000 patients every year, and apart from ordinary out-patient work of a gynaecological order, annually attends some 2,000 women in their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

Two other important obstetric and gynaecological hospitals in Dublin are the Coombe Lying-in Hospital and the National Maternity Hospital. During the year ending December 31st, 1927, the number of cases dealt with in the Coombe Lying-in Hospital were as follows: Intern maternity department, total admissions, 1,042, intern maternity department, total deliveries, 950, extern maternity department, total cases treated, 1,494, gynaecological department, number of operations, 462.

At the National Maternity Hospital, Holles Street, Dublin, during the year ending March 31st, 1928, there were admitted to the maternity department 941 patients, and to the gynaecological department 402, 709 calls were received in the extern obstetrical service, 866 patients were delivered in the hospital, and 628 in their homes, 378 operations were performed.

The practice of these hospitals is attended by large numbers of students, post-graduates, and nurses.

BELFAST

THE Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of bacteriology, biochemistry, biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a students' union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Bunn Ulster Eye, Ear and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Paradesburn, the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships—(1) Eight of the value of £40 each are assigned as Entrance Scholarships in the Faculties of Arts Science and Medicine tenable for one year. (2) fourteen Professional Scholarships, value from £15 to £40 each. (3) one Hutchison on Stewart

Scholarship, £12 in mental diseases. (4) one Mackay Wilson Travelling Scholarship, £100 awarded triennially. (5) Isabella Tod Memorial Scholarship tenable for three years, awarded triennially to a woman student. (6) Magrath Clinical Scholarship awarded annually value about £112. (7) two Musgrave Studentships of £200 in Physiology and Pathology. There is also a post-graduate research fund, open to all graduates of not more than three years standing. Gold medals are awarded at the M.D. examination.

Fees—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately £200. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty containing full information, can be obtained on application to the Secretary, Queen's University, Belfast, price 4d.

UNIVERSITY COLLEGE, CORK

THIS institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (130 beds), the County and City of Cork Lying-in Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglington Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well-equipped dental hospital in connexion with the school.

Scholarships—About £3,000 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees—The fees for the lectures and hospital attendances required by the National University of Ireland course including examination fees, come to about £170.

Further information can be found in the Calendar or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY

THIS institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of the London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £2,500, and the County Councils of Connemara offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connemara County Councils.

CLINICAL HOSPITALS IN ENGLAND

MANY hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Then honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house surgeons. These are usually paid offices, which may be held for periods varying from six months to a year, or even longer. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in those localities, but it should be added that there are many other provincial hospitals where admirable work is done, and in which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford, the Royal Sussex County Hospital, Brighton, the Royal United Hospital, Bath, the Kent and Canterbury Hospital, the Derbyshire Royal Infirmary, South Devon and East Cornwall Hospital, Plymouth, the Royal Albert Hospital and Eye Infirmary, Devonport, the Royal Devon and Exeter Hospital, the West of England Eye Infirmary, Exeter, the Gloucestershire Royal Infirmary and Eye Institution, the Royal Infirmary, Leicester, the County Hospital, Lincoln, the General Hospital, Northampton, the Norfolk and Norwich Hospital, the General Hospital, Nottingham, the Royal Portsmouth Hospital, the Royal Berks Hospital, Reading, the Royal South Hants and Southampton Hospital, the Staffordshire General Infirmary, Stafford, the North Staffordshire Infirmary at Hartshill, the Royal Hants County Hospital, Winchester, the Wolverhampton and Staffordshire General Hospital, the County Hospital, York, and the Coventry and Warwickshire Hospital.

London Clinical Hospitals

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

Children's Hospitals.—There are at least seven of these the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 263 beds. There are also the East London Hospital for Children, Shadwell, with 136 the Queen's Hospital for Children, Bethnal Green, with 134 the Victoria Hospital for Children, Chelsea, with 130 the Belgrave Hospital for Children, which has a considerable out-patient department and in-patient accommodation for 74 children, the Paddington Green Children's Hospital, and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women, Waterloo Road, S.E.1.

Hospitals for Women.—Queen Charlotte's Maternity Hospital, Marylebone Road, with 75 beds and a residential college for medical students and practitioners, specializes in the teaching of midwifery. The City of London Maternity Hospital, City Road, with 71 beds, also admits medical students and graduates to its practice. The Samaritan Hospital for Women, Marylebone Road, admits qualified practitioners as clinical assistants in both the in-patient and out-patient departments; demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s for three months. Full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Soho Square, whose teaching is confined to post-graduates in limited numbers; the Chelsea Hospital for Women, Arthur Street, Chelsea, and the Elizabeth Garrett Anderson Hospital for Women, Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road, E.C.1, 138 beds, 2,438 in patients, 51,841 out-patients in 1927. At this hospital two complete courses of instruction are given during the year—October to February, and March to July—comprising the following subjects: (1) anatomy (including histology and embryology), (2) physiology, (3) optics (including physiological optics), (4) refraction, (5) methods of examination and use of the ophthalmoscope, (6) pathology and bacteriology, (7) ophthalmic medicine and surgery, (8) ophthalmoscopic conditions, (9) operative surgery, (10) practical pathology, (11) practical bacteriology, (12) radiology, (13) physiotherapy (including ultra-violet light, diathermy and ionization), (14) slit lamp microscopy. A fee of 31 guineas will admit the holder once to all the lectures and classes except those on physiotherapy and slit lamp microscopy. The fee for a perpetual ticket to attend the practice of the hospital is £5 5s for three or six months, £3 3s for two months, £2 2s

for one month, £1 1s. Registered medical practitioners and medical students are eligible under certain conditions for the posts of chief clinical assistant, clinical assistant, and junior assistant. There are also a number of salaried posts, an annual Clinical Research Scholarship of £50, and a biennial Gifford Edmonds Prize of £100. Clinical work begins each morning at 9 and operations at 10 o'clock. The course of instruction is specially adapted to meet the requirements of those reading for the D.O.M.s and similar diplomas and degrees in ophthalmology. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital, the Royal Eye Hospital, Southwark, and the Central London Ophthalmic Hospital, Judd Street, W.C.1, each with about 40 beds, and the Western Ophthalmic Hospital with 18 beds.

Fever Hospitals.—The Metropolitan Asylums Board has under its control a good many institutions in and around London for the treatment of the more serious zymotic disorders. It makes special arrangements for the instruction of students in this subject and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment, E.C.4.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Framley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 185 beds, and the Royal Hospital for Diseases of the Chest, City Road, with 85 beds now amalgamated with the Royal Northern Hospital, Holloway Road.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square, the Royal Ear Hospital, Dean Street, the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road, and the Hospital for Diseases of the Throat, Golden Square—the last which possesses 75 beds being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, St. George's Fields, S.E.1, which (like the Maudsley Hospital) confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; the Royal National Orthopaedic Hospital, Great Portland Street; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; the National Hospital, Queen Square, W.C.1, an institution possessing 200 beds for neurological cases and a world-wide reputation; and the West End Hospital for Nervous Diseases, 73 Welbeck Street, W.1.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

WOMEN IN MEDICINE

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

EXAMINATIONS

Women are admitted to all the medical examinations of the following qualifying bodies: all the universities of Great Britain and Ireland, the Royal College of Physicians, London, the Royal College of Surgeons of England, the Society of Apothecaries of London and the Conjoint Boards in Scotland and in Ireland. In addition, women are eligible for election as Fellows to the Royal College of Physicians, England, and the Royal College of Physicians, Edinburgh, and the first woman has recently been elected by the latter.

MEDICAL EDUCATION

The general tendency during the years since the war has been to admit women to train in medicine at the same schools and under very much the same conditions as men. In this country at the present time co-education is the general rule. The schools of the London hospitals have, however, so far shown themselves more conservative in this respect than the rest of the country.

In England the colleges connected with the universities of Birmingham, Bristol, Cardiff, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women students as well as men, whilst in Scotland the universities of Aberdeen, St. Andrews, Edinburgh, and Glasgow also admit women. In Ireland all universities and colleges are open to them.

In London several of the old-established hospitals opened their doors to women students during the war, but are

showing a tendency at the present time to revert to their previous status of schools for men only. This is an unsatisfactory state of affairs, which it appears can only be temporary, no unsatisfactory results of co-education having been brought forward by any of the schools so closing their doors to women.

At the present time the only co-education hospital in London is that of University College—the number of women entrants is restricted to twelve a year, but these twelve (making between thirty-six and forty-eight training at any one time for the three to four years' clinical course) are given excellent opportunities whilst students, and also, in fair proportion, are given opportunities of post-graduate experience as residents—house-surgeons, house-physicians, and obstetrical assistants.

THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The London (Royal Free Hospital) School was started for the training of women in medicine in the days before there were any co-education facilities for them, and it still remains by far the largest school for women. In addition to the clinical work at the Royal Free Hospital arrangements are made for students of the school to obtain clinical instruction at the National Hospital for Nervous Diseases, Queen Square, the Royal London Ophthalmic Hospital, Moorfields, the Great Ormond Street Hospital for Children, the Elizabeth Garrett Anderson Hospital, the South London Hospital for Women, and the Cancer Hospital. Its importance for women in medicine can hardly be overestimated, not merely because it was the pioneer which made the way possible, but also because it is still the only general hospital in Britain which offers all its post-graduate appointments, higher and lower, to open competition by women as well as men, thus giving unique opportunity of gaining experience. Not only are all the resident appointments at the Royal Free Hospital, of which there are twenty-seven yearly, eligible for women, but, in addition, higher posts may be obtained in all the various branches of a general hospital, from those of registrar and anaesthetist to those of visiting physician or surgeon and those in charge of special departments. There is a special unit in gynaecology under a woman professor, and entirely staffed by medical women. This policy has so far not been fully adopted in its entirety by any other hospital, and it may be of interest to note in this connection that the Royal Free Hospital has many women on its general committee and weekly board of management.

OPENINGS FOR MEDICAL WOMEN

There are at the present time the names of over three thousand medical women on the *Medical Register*. Owing to the artificially stimulated demand for women to enter medicine during the latter part of the war, there was, for a short time, a greater number of women qualifying than could be readily absorbed in the various branches of medical work. This was, however, purely transitory, and the demand now is approximately as great as the supply. There is an increasing demand by the public for the services of women doctors in all branches of medicine, and statistics show that the number of those who make good is as high, if not somewhat higher, than that of their men colleagues.

OPENINGS AT HOME

House Appointments—The valuable post-graduate experience obtained in these posts is eagerly sought by both men and women, and it is therefore only to be expected that the increase in the number available to women should be gradual. In addition to the Royal Free Hospital, where by far the greatest number are available, the co-education hospitals show an increasing tendency to admit their women graduates in due proportion to these posts, and in addition women are appointed as residents in many of the non-teaching general hospitals, hospitals for women and children, sanatoriums, infirmaries, fever hospitals, and asylums.

General Practice—There are good openings as assistants or, better still, as assistants with a view to admission as

partners in general practice. Medical women also do very well when starting in new districts, and there is considerable scope for them in midwifery work.

Specialist and Consulting Practice—This naturally only becomes possible as hospitals admit women as physicians on their honorary staffs, in this respect the Elizabeth Garrett Anderson Hospital and the South London Hospital for Women have rendered invaluable service to women in medicine. As has been mentioned, the Royal Free Hospital also has a considerable number of women on the staff, whilst in the provinces women are making satisfactory progress in this direction. To mention a few—at Bath, Bristol, Edinburgh, Glasgow, Hereford, Liverpool, and Manchester—there are women on the honorary visiting staffs of general hospitals and special hospitals as general physicians, surgeons, gynaecologists, orthopaedic surgeons, children's specialists, and infants' specialists. It is interesting to note that there are already women in successful practice as consulting physicians, surgeons, gynaecologists, ophthalmologists, ear, nose, and throat specialists, urologists, dermatologists, anaesthetists, tuberculosis specialists, venereal disease specialists, x-ray and light treatment specialists, psychologists, specialists in orthopaedic work, children's diseases, bacteriology and pathology, and spa treatment, etc. Research work also provides interesting openings, as, for example, in dealing with the special problems concerning cancer, nutrition, puerperal morbidity and mortality, statistical work, etc., and for some of these research scholarships and grants are available.

Teaching Posts—Women hold professorships and lectureships at various universities.

Industrial Medicine—In this branch there is much interesting work available, and it is undergoing considerable development at the present time. Several women already hold such posts.

Administrative Work—A certain number of these important posts are admirably filled by medical women. The chief medical officer for maternity and child welfare is a medical woman and has a staff of medical women to assist her.

The Public Health Service—This service provides numerous openings for medical women. It has many departments, and its rapid growth in recent years has provided much interesting work in preventive medicine. For maternity and child welfare work women have been found to be peculiarly suited, but, by a curious economic limitation, married women, who would appear to be the most suitable of all, are, by many public authorities, excluded from service. This exclusion not only prevents married women from taking part in this work, but also prevents many of the best women from specializing in this branch of medicine, as it is obviously uneconomical to specialize in a branch of public service from which one may be excluded in a few years.

Medical Inspection, etc.—Under the Board of Education there are women serving as medical advisers and school medical inspectors. The London County Council and other important councils in the country have medical women on their permanent medical staffs, both in the senior and junior grades. The London County Council has two of its senior medical women appointed to serve as district medical inspectors. In addition, they have a large number of women medical inspectors of school children, and also women are serving as experts in the departments dealing with mental deficiency, tuberculosis, and venereal disease. Some medical women also serve as examiners of the candidates entering the public services, as, for example, the civil service. The services of medical women are extensively enlisted by public authorities in dealing with employees of their own sex. In several instances women serve as assistant medical officers to prisons, and in one instance at least a woman has recently been appointed as the medical officer for the police women of a large city. The services of medical women are also enlisted as lecturers and examiners on first aid, home nursing, health, and infant care.

PAY AND STATUS

It is interesting to note that medical women, backed by the powerful assistance of the British Medical Association, have been on the whole successful in resisting the attempt to accept a lower salary for the same work as their men colleagues, thereby not only greatly benefiting themselves, but also maintaining the standard for the whole profession. They realize that over since the admission of women to the medical profession exactly the same sacrifices for principle have been made by their predecessors as are now demanded from them. With the inauguration of the School Medical Service in 1908, and later when maternity and child welfare posts were created, persistent efforts were made by local authorities to pay their assistant medical officers below the minimum arranged by the representatives of the public authorities and the British Medical Association, and to secure women at a lower rate than men. With rare exceptions these efforts were a failure. Women realize as clearly as men that lowered pay invariably implies a lowered status and prestige, and that the woman who stamps herself as belonging to an inferior grade of doctor cannot complain if she is taken at her own valuation, and that a minimum always tends to become a maximum. Attempts to evade the scale and split the ranks of the profession by offering a post to a man at the agreed rate and a similar post to a woman slightly below that rate are particularly to be deprecated. Where the rule of equal pay for equal work is violated there is no limit to the extent to which women may be exploited and sweated.

An interesting extension of public health work has recently occurred by which a temporary exchange of posts has been arranged for one year between a woman assistant school medical officer to the London County Council and a woman medical officer attached to the health department of Western Australia.

OPENINGS ABROAD

Colonial Office—To those to whom overseas service appeals it offers the possibility of useful, interesting, and adequately paid work. At present there are only posts for women in Malaya and West Africa, and the work is almost entirely hospital and maternity and child welfare work, there have been one or two specialist appointments, such as bacteriologists, and more may follow. Women have, so far, only been appointed to the lower grade posts, but their pay is the same as that of the men in similar grades. When placed on the permanent staff they are eligible for pension.

Egypt—Several posts are held under the education authority, chiefly in school medical inspection.

India—See note on the Women's Medical Service for India in the next column.

Mission Field—Missionary societies offer employment to medical women, chiefly in India, China, and the Near East.

PUBLIC ACTIVITIES

Medical women have always shown considerable interest in medico-political affairs, and take an active part in the work of the British Medical Association, and with the various other societies dealing with medicine as it affects the community in general. With this end in view they also have a Medical Women's Federation, which enables them to voice a collective expression of opinion. This might otherwise be difficult to ascertain as women are so widely scattered, both as regards their geographical distribution and their varied activities. This collective opinion of medical women has been found of great assistance by the British Medical Association and other allied societies with which it works in cordial co-operation and by whom it is frequently approached, both for information and also as a convenient means of approaching medical women as a whole.

It may be added, with regard to contributions to medical literature, that this is a branch of work in which women are more and more taking their share, and scientific and other works are frequently published by them.

WOMEN'S MEDICAL SERVICE FOR INDIA

THIS service is open to properly qualified medical women of British or Indian nationality who desire to carry on work in India. It was founded in 1913 by the Countess of Dufferin's Fund, the committee of which was granted a subsidy of 1½ lakhs (£10,000) by the Government of India for this purpose.

Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals.

Private practice is always allowed after the first two years provided it does not interfere with official duties. The only exception is in administrative posts, when an allowance in lieu of practice is given. The amount obtained by practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1,000 a year. Excellent opportunities for surgery—especially gynaecological—are found in the Women's Medical Service. The prevalence of osteomalacia in some parts of the country leads to the necessity for frequent Caesarean section, while uterine fibroids, ovarian tumours, and diseased tubes swell the number of abdominal operations. The number of large operations performed will vary with the surgical reputation of the medical woman, but in some cases it is considerable.

To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare. The high infant mortality and the suffering of women in childbirth owing to the ignorance of the not-trained hereditary midwives provide a great field for such workers. Medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Years of Service		Rates of Pay per mensem	Annual Salary
1-3	..	Rs. 450	£360
4-6		Rs. 500	£400
7-8	..	Rs. 550	£440
10-12	..	Rs. 600	£480
13-15	..	Rs. 650	£520
16-18	..	Rs. 700	£560
19-21	..	Rs. 750	£600
22-24	..	Rs. 800	£640
Over 24		Rs. 850	£680

Furnished quarters are provided also an overseas allowance of Rs.100 per annum the rupee value being taken at 1s 4d.

The above rates of pay are not so high as in the Indian Medical Service. The fact however that furnished quarters are provided (these are not provided in the Indian Medical Service) represents an additional Rs 150 per mensem. It must be remembered too, that the official duties of the members of the Women's Medical Service are lighter than those of the Indian Medical Service, who while in civil employ, in addition to work in the Civil Hospital, have charge of the medico-legal work of the district give much gratuitous attendance, and form a reserve to be drawn on in time of war.

The cost of living in India is much higher than formally, but even now it is possible to live more cheaply than in England for the same measure of comfort. The cost of all goods brought from Europe is very high but the cost of country produce is much less than in Europe. Meat poultry milk, eggs, etc., are sold at about half the price now demanded in England. It should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs 200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expenses for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half pay at the rate of two months for every year of service is granted after every three years.

Study leave on furlough pay and lodging allowance at the rate of 12s per day may be granted to the extent of twelve months in the total service.

There is a Provident Fund to which members of the service contribute 10 per cent of their pay. The service contributes another 10 per cent which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Honorary Secretary, U.K. Branch of the Countess of Dufferin's Fund c/o Major General J. B. Smith, India Office, Whitehall, S.W.1.

POST-GRADUATE STUDY

In the matter of facilities for post-graduate medical study little change has taken place since last year, when the Minister of Health, Mr. Neville Chamberlain, made it clear that in his own mind it was practically settled that the West London Hospital at Hammersmith would be organized as the centre of post-graduate medical education in London. No report, however, has yet been issued by the committee appointed by the Minister of Health some three years ago to inquire into the matter. Thus it is that only one of the two recommendations made by the committee appointed by Dr. Christopher Addison, when Minister of Health, and presided over by the Earl of Athlone, has materialized. The building of the School of Hygiene and Tropical Medicine in Bloomsbury, made possible by the generous contributions of the Rockefeller Foundation, is now approaching completion, and is likely soon to be available for teaching under Dr. Andrew Balfour, the Director, and the professorial staff associated with him. Particulars of this school are given on page 411.

The "hospital centrally situated in London, devoted solely to post-graduate medical education as a school of the University," is not yet organized. There are, however, several institutions both in London and elsewhere which seek to provide for the wants of graduates, whether desirous of refresher courses, of instruction in special subjects with a view to obtaining one of the special diplomas, or of preparation for examination for promotion in one or other of the Services. Thus the Fellowship of Medicine, founded in 1918, and amalgamated with the Post-Graduate Medical Association in 1919, has an office generously placed at its disposal by the Royal Society of Medicine at 1, Wimpole Street, W.1. A list of hospitals, special and general, to which post-graduates may resort, with or without fee, is kept, and the names of the teachers at each hospital are available. From time to time courses in special subjects are arranged. The West London Hospital at Hammersmith, and the Prince of Wales's General Hospital at Tottenham, have for many years past had post-graduate colleges attached to them. Several special hospitals provide post-graduate courses during the year, while many of the undergraduate schools give facilities for attending classes and demonstrations, though mostly to their own old students.

In the provinces the Universities of Oxford, Cambridge, Birmingham, Bristol, Liverpool, Manchester, and Sheffield have organized courses. Edinburgh receives graduates from many schools in the Dominions as well as in this country. In Glasgow and Aberdeen courses are available, and in relation with the University of St. Andrews courses are given by the staff of the James Mackenzie Institute for Clinical Research. At many of these centres the teaching is provided by way of whole-time intensive courses, by part-time courses, or by means of clinical assistantships. The Joint Tuberculosis Council has provided nomadic courses in its own special subject.

There is evidence, therefore, of considerable post-graduate activity in this country, although it lacks the cohesion and concentration displayed in such a centre as Vienna. This is accounted for, no doubt, by the multiplicity of hospitals engaged in the task, and the lack of any central body responsible for post-graduate education as a whole. This view was put forward very strongly in the article on "Australia and New Zealand and our duty thereto," by Mr. Victor Bonner, which was published in the *British Medical Journal* of July 21st last. It was reiterated with at least equal emphasis by several representatives from Overseas Dominions during the recent Annual Meeting of the Representative Body of the British Medical Association at Cardiff. Mr. Bonner asserted that the need to improve our post-graduate facilities was very great. In his opinion

the prime requirement was a large central hospital devoted solely to post-graduate work. But pending the development of such a hospital he thought that a great deal more could be done in promoting post-graduate study by concerted effort, and that both for professional and for national reasons the urgent need for such effort should be realized.

The following passage from the Presidential Address to the British Medical Association this summer seems very much to the point:

"There is an impression abroad—and it is not, perhaps, ill founded—that in the British Isles we do not sufficiently organize and utilize the wealth of clinical material at our disposal for post-graduate demonstration in the interests of our home profession and of visitors from other countries. Good work has been and is being done in the various metropolitan centres, but these do not claim a monopoly of skill and clinical facilities. I have long felt that, with its wonderfully ramified machinery to link up the provinces and the capital, the rural areas and the towns, no body is so well adapted as our Association to organize a post-graduate system embracing existing institutions and developing many new centres, on a scale worthy of this country."

Meanwhile, in the absence of any comprehensive co-ordinating schemes, opportunities are fairly numerous and varied for the would-be student who troubles to seek out the course which he requires. Short particulars about post-graduate study in Great Britain and Ireland are given in Section VI of the *Handbook for Recently Qualified Practitioners* published by the British Medical Association (price 3s. 6d.).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION

The Fellowship of Medicine has arranged regular courses in general medicine and surgery, including special departments, each lasting two weeks, the fee for each course is 3 to 5 guineas. Courses in diseases of the chest, children, ante-natal, heart, nervous system, throat, nose, and ear, dermatology, electrotherapy, gynaecology, proctology, psychological medicine, tropical medicine, urology, and venereal diseases are given from time to time at the special hospitals in association with the Fellowship of Medicine. The Fellowship Programme contains a diary of the arrangements available for post-graduates in various general and special hospitals in London. The programme for the immediate future includes a two weeks' course in general medicine and surgery, from September 17th to 29th, at the Westminster Hospital. There will also be special courses in diseases of children at the Queen's Hospital from September 17th to 29th, in ophthalmology at the Royal Eye Hospital from September 17th to 29th, in psychological medicine at the Bethlem Royal Hospital from September 4th to 29th, and a course in orthopaedics at the Royal National Orthopaedic Hospital from September 17th to 29th. The offices of the Fellowship are, by kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W.1 (telephone, Mayfair 2236). The secretary is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s., which includes the subscription to the *Post Graduate Medical Journal*.

The Fellowship arranges, during the autumn and winter sessions, a series of lectures. Special clinical demonstrations in medicine, in surgery, and in ophthalmology are arranged also weekly from October onwards. Syllabuses will be sent regularly on application.

WEST LONDON POST GRADUATE COLLEGE

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, it is provided with lecture reading writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. The work of the college is eminently suitable for men in

General practice and officers in the services who wish to revise their general clinical knowledge.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months, no charge being made. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal diseases, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist, who attends every day.

Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

Fees—Hospital practice, including all ordinary demonstrations and lectures £1 11s. 6d. for one week £4 4s. for one month £7 7s. for two months £9 9s. for three months, £15 15s. for six months, £23 12s. 6d. for one year and £45 for a life ticket. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, Tottenham, N. 15, in the midst of this densely populated North London district. It contains 200 beds, and is within a few minutes' walk of South Tottenham Station on the London Midland and Scottish Railway and Seven Sisters and Tottenham Hale Stations on the London and North-Eastern Railway. It is readily accessible by electric tram from Finsbury Park and Hackney, and from Dalston, Edmonton, and other parts of North London.

The college is in association with the Fellowship of Medicine and Post-Graduate Medical Association, and is recognized by the Admiralty and India Office for the purpose of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees, the course of practical teaching of bacteriology is approved by the University of Cambridge for its Diploma in Public Health, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital as a whole affords excellent facilities for qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions, into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff. Operations are performed every afternoon of the week except Saturday. Special vacation or intensive courses are held at intervals throughout the year, each lasting two weeks, clinical instruction being arranged for each hour of each day.

Fees—Two guineas for three months attendance in any one department which may be begun at any time, a fee of 5 guineas admits to the whole practice of the hospital for a similar term (one month 2 guineas, and one year 10 guineas), and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

The winter session will be opened about the middle of September as regards clinical teaching.

Additional information can be obtained from the Dean of the Post-Graduate College, of the hospital.

MANCHESTER POST-GRADUATE COURSES

The Faculty of Medicine of the University of Manchester has arranged courses in preparation for the diplomas in psychological medicine, in public health, bacteriology, and veterinary State medicine. There are classes also for certificates in factory and school hygiene and in venereal diseases. The Faculty of Medicine has also instituted courses to meet the requirements of graduates desiring to refresh their knowledge or to pursue further their studies in various special branches. The arrangements are in the hands of a committee consisting of certain members of the faculty, of representatives of hospitals, and of the medical officer of health for Manchester. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester. A whole-time intensive course in general medicine and surgery will begin on September 10th and continue until September 29th, and an intensive course in obstetrics and gynaecology will be given from September 29th to October 6th. Part-time courses in certain subjects have also been arranged, including diseases of the eye, diseases of the skin, the application of radiology to medicine in diagnosis and treatment, and clinical pathology. A limited number of clinical assistantships are offered in the medical, surgical, and special departments of the Manchester Royal Infirmary, the Ancoats Hospital, and certain special hospitals for one, two, or three months, or longer.

COURSES FOR MEDICAL GRADUATES AT BRISTOL

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

Daily Post-Graduate Study—For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and *post-mortem* examinations.

Post-Graduate Clinical Work—Demonstration courses with weekly lectures are held during May, June, and July. All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

NEWCASTLE-ON-TYNE

For the year 1928-29 the following post-graduate courses have been arranged by the College of Medicine, Newcastle-on-Tyne (University of Durham).

1. General courses in clinical medicine, surgery and pathology at the Royal Victoria Infirmary meeting once weekly for ten weeks. One course will be held from October to December, and one from April to June.

2. Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: Gynaecology, diseases of the eye, diseases of the throat, nose and ear, diseases of the skin, venereal diseases, neurology.

Special courses in midwifery will be held at the Princess Mary Maternity Hospital.

3 An intensive course of fourteen days duration in the early part of the summer vacation, 1929

4 In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary and also at the Princess Mary Maternity Hospital, for specified periods

EDINBURGH POST-GRADUATE COURSES

In connexion with the University and Royal Colleges post-graduate courses are arranged every year, from about the middle of July to about the middle of September, comprising (a) A course in obstetrics and gynaecology, generally held from about the middle of July, (b) a general practitioners' course, (c) a general surgical course. Courses (b) and (c) extended for four weeks from August 13th to September 15th. Similar courses are held each year.

The course in obstetrics and gynaecology comprises instruction in clinical midwifery and clinical gynaecology, obstetrics and gynaecological pathology, child welfare and ante-natal clinics, etc.

The general practitioners' course includes lecture demonstrations, and, where possible, practical instruction on medical anatomy, medical sideroom work, examination of the blood, x-ray and electrical therapy, morbid anatomy, and post-mortem examination, clinical instruction in medicine, surgery, gynaecology, diseases of children, diseases of the skin, and infectious diseases, and special instruction in the diseases and methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems, and in diseases of the ductless glands. The general surgical course includes lecture demonstrations on surgical anatomy, surgical pathology, and surgical x-ray diagnosis, clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children, clinical instruction in venereal diseases, surgical out-patients, surgical and gynaecological operations and special instruction in abdominal and genito-urinary and other branches of surgery.

A series of special lectures, open to all graduates, is delivered on subjects of general medical and surgical interest, including recent advances in treatment. Among the special courses also arranged are examination of the blood, vaccine therapy, clinical chemistry, diseases of the ear, nose, and throat, and venereal diseases.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

POST-GRADUATE MEDICAL TEACHING IN GLASGOW

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association is composed of practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, Bt., and the vice-chairman Sir Hector C. Cameron. During the winter months special courses in various subjects are conducted, and from November till May there is a series of weekly demonstrations specially designed for local practitioners. A comprehensive scheme of clinical courses is carried out during the summer months, from June till October, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed.

A general medical and surgical course is now held each year during the last two weeks of August and the first two weeks of September, which is arranged to include most of the subjects of interest to the general practitioner. This year the course is being conducted from August 20th to September 15th. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in the special hospitals and in the special departments of the General Hospitals, two subjects being considered most after-

noons. On the four Saturday forenoons psychological medicine will be demonstrated at Duke Street Hospital and at Gartnavel Mental Hospital.

Further information may be had on application to Dr James Carslaw, Secretary, Post-Graduate Medical Association, 9, Woodside Terrace, Glasgow, C 3.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION

The Australian and New Zealand Medical Association gives information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S. (England and Edinburgh), and the D.P.H., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. Two dinners are held annually. All medical graduates or undergraduates born in Australia or New Zealand and resident in or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr E. T. C. Milligan, F.R.C.S., and Mr Philip J. Jory, F.R.C.S., 86, Harley Street, London, W.1.

TROPICAL MEDICINE

THERE are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees is given in the paragraphs printed below. Further particulars will be found in the *Guide to Regulations, Courses, and Qualifications in Public Health and Tropical Medicine and Hygiene*, compiled by Dr Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, and published by the British Medical Association (price 3s.). This useful handbook contains, among other matter, a list of the teaching centres and examining bodies, with the qualifications obtainable from them. The University of London alone gives a degree (M.D.) in Tropical Medicine, and this, being an "internal degree," can only be taken by students who are medical graduates of that university. Diplomas in Tropical Medicine or Hygiene are granted by the universities of Cambridge, Edinburgh, and Liverpool, and by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England.

DIPLOMAS AND DEGREES

LONDON UNIVERSITY—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

THE EXAMINING BOARD IN ENGLAND—This body grants a diploma in tropical medicine and hygiene to candidates after an examination held in the months of February and July. Candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine, in an institution recognized for this purpose, during not less than five months, (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than five months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 9s. The Board also grants diplomas in public health, in psychological medicine, in ophthalmic medicine and surgery, and in laryngology and otology. Candidates must hold a medical qualification registrable in the United

Kingdom or be graduates in medicine of a recognized Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, London, W C 1.

UNIVERSITY OF LIVERPOOL—A diploma in tropical medicine is given by this university to students who have attended the courses provided by the Liverpool School of Tropical Medicine and have passed the examination held twice yearly by the university examiners. The subjects of examination are (a) tropical pathology and parasitology, (b) entomology, (c) tropical medicine, including etiology, symptoms, diagnosis, and treatment of tropical diseases. Fee for the course, £21. A diploma in tropical hygiene (D T H), open to the holders of the D T M, has recently been established. The subjects of examination are bacteriology, chemistry (including meteorology and climatology), zoology, tropical sanitation (including practical sanitation, sanitary engineering, statistics. Fee for the course, £10 10s. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF CAMBRIDGE—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examinations of the university in this subject. Candidates for Part I are examined in the same subjects as candidates for Part II. The Diploma in Public Health. Before admission to Part II, the subjects for which are medicine, surgery, and hygiene in their relation to tropical diseases, candidates must have passed Part I. An examination for Part I is held in April and for Part II in July. The fee for each part of the examination is 10 guineas. Application for further information should be made to Mr J. L. Purvis, Public Health Chemical Laboratory, Medical School, Cambridge.

UNIVERSITY OF EDINBURGH—Candidates for the Diploma in Tropical Medicine and Hygiene granted by the University of Edinburgh must be graduates in medicine and surgery of that university, or hold corresponding registrable degrees or qualifications of some other licensing body. The course of instruction extends over two terms, and may be taken either from October to March or from April to June and January to March. The examinations are written, oral, and practical, and are held at the end of the courses. Candidates are required on the first occasion of presenting themselves for examination to appear for all the subjects. Those who fail to pass the entire examination within a period of twelve months after first appearance are required to reappear for all the subjects. The university is included in the list of institutions whose courses of instruction in Tropical Medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

SCHOOLS

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (UNIVERSITY OF LONDON)

The London School of Hygiene and Tropical Medicine is a school of the university in so far as its active departments are concerned—namely, the Department of Bacteriology and Immunology, the Department of Epidemiology and Vital Statistics and the Departments concerned with the teaching of Tropical Medicine and Hygiene. An advanced course of study for the Diploma in Bacteriology intended for a limited number of post-graduate students and lasting for one academic year, will commence on October 9th 1928 and courses of instruction (minimum period three months) in the application of statistical methods to the problems of Epidemiology and Public Health Administration will also be given, commencing in October. The work which prior to August 1st, 1924 was carried on by the London School of Tropical Medicine continues for the present in the building occupied by the Hospital for Tropical Diseases at Eadsleigh Gardens, W C 1, where the specially equipped laboratories, museum, library,

and clinical facilities afford excellent opportunities to those who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the wards of the Hospital for Tropical Diseases are to be found cases such as may be met with in actual practice in the tropics. There are two courses in the year, each lasting twenty weeks, beginning October 1st, 1928 and March 11th, 1929 respectively. The course is so arranged as to equip men for the D T M and H of the Conjoint Board. There are advanced courses in the several subjects and a special course in parasitology for D P H students and for the first part of the D T M and H Camb. Clinical instruction is also provided for the second part of the D T M and H Camb. Tropical medicine is a sixth alternative subject for the M D of the University of London, and the school curriculum is adapted to afford facilities for candidates desirous of taking the M D in this subject. The course in Tropical Hygiene may be taken separately, if desired. Research studentships and scholarships are available. The new building in which the school will be housed is approaching completion, and the formal opening and the commencement of the new courses of study—in particular, that for the D P H—will probably be in the summer or autumn of next year. Further information may be obtained from the Secretary, London School of Hygiene and Tropical Medicine, Malet Street, London, W C 1.

THE UNIVERSITY OF EDINBURGH

A course of instruction for the diploma comprising a primary and a second course is given during the autumn and spring terms (October to March), and includes tropical hygiene, bacteriology, entomology, and parasitology, diseases of tropical climates (systematic and clinical), tuberculosis, and venereal diseases. The primary course alone is also given during the summer term, April to June. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE

This school is affiliated with the University of Liverpool. The university now grants diplomas in tropical medicine (D T M) and in tropical hygiene (D T H).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D T M, commencing respectively October 1st (autumn term) and January 7th (lent term), and two courses for the D T H, beginning on January 7th and April 22nd (summer term). The D T H can only be taken by those who have obtained the D T M. Students who do not desire to take the diploma examinations held by the university at the end of each term are given a certificate if attendance has been satisfactory.

Fees—(1) For the D T M course 20 guineas for the D T H course 10 guineas. (2) For the diploma examinations 5 guineas. An extra charge of one guinea is made for the use of a microscope if required.

The new laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has (1) lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms, in which are housed the Departments of Tropical Medicine and Entomology. The second floor has the main class laboratory, 69 feet by 58 feet, excellently lighted and three other rooms devoted to the Department of Parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proof house and other accommodation.

Since its foundation the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-one special memoirs—in the *Annals of Tropical Medicine and*

Parasitology, issued by the school, and in numerous articles in the scientific press

The school has also two laboratories in the tropics: the Manáes Research Laboratory in Brazil, and the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone, which was opened on January 10th, 1922, and is staffed by the school. Further information may be obtained from the Honorary Dean, School of Tropical Medicine, Pembroke Place, Liverpool

PSYCHOLOGICAL MEDICINE

It cannot be impressed too strongly upon the medical student that a knowledge of mental disorder is just as essential as a knowledge of the other forms of disease which he will be called upon to treat in the routine of general practice. It must be understood that by the term "mental disorder" is not only meant those severe forms which are to be found in mental hospitals, but the term also includes mental defectives of all grades, nervous, difficult, and backward children, the mild and often unrecognized psychoses, and also the various types of psychoneurosis. Such disorders provide the general practitioner with a large proportion of his most difficult cases, and he will find a good knowledge of mental disorder invaluable in his work. Apart from general practice, the student who proposes to take up a career in the prison service or, still more importantly, the school medical service, will find a knowledge of psychological medicine an almost essential part of his equipment.

Instruction

"It is more than a little surprising that despite the greatly increased interest in psychology that has developed in recent years, especially in the decade since the war, no corresponding change is evident in the curriculum laid down for the psychiatric training of medical students in this country."

Though at the present time the instruction given to the student is far from adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given on psychopathology. These facilities need not be utilized by the student, however, and (as indicated in the passage quoted above) the compulsory part of the curriculum is confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the terminal states of mental disease, and he is also apt to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders, where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

A scheme is now in actual operation at the Middlesex Hospital in which a small number of mental cases are treated in the hospital as in-patients. This is an important move from the teaching point of view, because the student will gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital, and at the National Hospital, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also at the Universities of Glasgow, Birmingham, Leeds, Manchester, Durham, and elsewhere.

Diplomas

Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine (D.P.M.), to which reference has been made, can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, Dublin, and the National University of Ireland, and from the Conjoint Board in England. The Royal Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination, and encourages the study of psychiatry by the offer of prizes for original and research work.

The requirements for a diploma differ to some extent in the various universities and colleges, but the following model scheme suggested by the Royal Medico-Psychological Association, and already adopted by the Royal College of Physicians of Ireland, will give an indication of the scope of the examination for a diploma.

Model Scheme for a Diploma in Psychological Medicine

- 1 The candidate must be already a registered medical practitioner.
- 2 The candidate may present himself for examination on the subjects detailed under Part I of the curriculum (see para 4) immediately he has concluded the prescribed course of instruction or can produce such other evidence of diligent study of the subjects to be examined upon as may be demanded. Part I must be passed save by special permission at least three months prior to entering for examination on Part II of the curriculum.
- 3 The candidate may not present himself for examination on the subjects detailed under Part II of the curriculum (see para 4) until he has been a registered medical practitioner for not less than two years. He must subsequently to qualification have been in the practice of an approved mental hospital for not less than two years or have attended for six months at a hospital, mental or general for clinical instruction in psychological medicine and subsequently held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognized source that he can apply his theoretical knowledge, and has practical acquaintance with, and is well and adequately versed in the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended subsequently to qualification courses of lectures, demonstrations or other evidence of diligent study of the subjects upon which he presents himself for Part II of the examination, as may be demanded.
- 4 Curriculum. Part I—(a) Anatomy, histology and physiology of the nervous system including the autonomic system, anatomy and physiology of the endocrine glands, chemistry and cytology of the cerebro-spinal fluid. (b) Psychology, systematic and experimental. Part II—(a) Morbid anatomy, histology and pathology of the systems mentioned under Part I. (a) *post mortem* and laboratory technique. (b) neurology and clinical neurology. (c) psychiatry (including the psychoneuroses), clinical psychiatry and the medico-legal relationships of mental disorders and mental deficiency. In addition the candidate for Part II will need to show special knowledge of any one subject to be selected by him from the subjects comprising Part I or Part II or may choose to be examined in any one of the following subjects: (d) Mental deficiency and the mental disorders of childhood and adolescence and the duties of school medical officers in relation thereto. (e) Bacteriology as applied to mental and nervous disease. (f) Psychopathology and psychotherapy. (g) The principles of diet, vitamins and basal metabolism, and their application. (h) Eugenics and vital statistics. (i) Criminology and the juris prudence of criminal responsibility.
- 5 The diploma, by request may be endorsed that special knowledge has been shown in the subject selected.
- 6 It is suggested that any compulsory attendance at lectures or demonstrations and clinical courses should be limited to the subjects detailed for Part II and that the course for Part I or Part II should not exceed eight weeks.

Mental Hospital Appointments

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions such as those under the control of the London County Council where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself.

or a residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition, if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital and draw various allowances.

Since the passing of the Asylum Officers' Superannuation Act of 1909, all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fiftieth for every year served, paying as contribution 3 per cent of the value of their appointments annually. This very favourable prospect may not appeal to junior practitioners joining the services, but will eventually prove to be a valuable asset.

Prospects in the Public Service

Appointments to the public mental hospitals are made by the visiting committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local and, except indirectly, not an imperial one, the promotion tends to be slow and uncertain, and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in years past, but the general conditions of service have tended to show a progressive improvement and will in all probability continue to do so in the future.

Both the British Medical Association and the Royal Medico-Psychological Association are working separately and together to improve present conditions of service, and have, for example, already removed the "climax" objection to the service. The salaries have also been considerably increased, especially in the junior ranks, and contrast favourably with those which were paid before the war. During the last few years considerable progress has been made in the conditions under which the insane are treated. The mental hospitals are developing an atmosphere approximating more closely to that of the general hospitals. As a result of these developments the mental hospital service is becoming more attractive, and now affords greater opportunities for the medical graduate who proposes to specialize in psychiatry.

While routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, time, and scope for purely medical work and research—difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates. Most mental hospitals are now equipped with efficient clinical laboratories, moreover, those who wish to undertake research are afforded every opportunity of doing so in the pathological department of the Maudsley Hospital and also in various other centres in England and Scotland. A change in the law, in which power was given to local authorities to make provision for the treatment of early and acute cases of mental disorder without certification, would do much to make psychiatric work more attractive to medical men. If this alteration in the law were made, hospitals, either in the precincts or the grounds of the county or borough mental hospitals, or in adjacent towns, would be erected in the course of time, or wards in general hospitals might be utilized for the same purpose. Such clinics would render appointments in mental hospitals more attractive because the work would be entirely free from the custodial aspects of mental disorder, and attention could be given by the physician to purely medical problems without irksome legal restrictions.

MAUDSLEY HOSPITAL, DENMARK HILL

A course of instruction for the Diploma in Psychological Medicine is given annually at the Maudsley Hospital from January to May inclusive, the details of the last course

being as follows. The course consisted of two parts. In the first part lectures on the anatomy of the nervous system were given by Professor Elliot Smith, with practical instruction by Mr C. Geary. A course of lectures on the physiology of the nervous system, with demonstrations in physiological psychology, was given by Dr F. Golla, a series of lectures and demonstrations on the biochemical aspects of mental disorders, and laboratory methods, by Captain S. A. Mann, and on theoretical and practical psychology by Dr Henry Devine. For the second part of the course lectures on morbid psychology and psychiatry were given by Dr Mapother, on the neuroses by Dr Bernard Hart, on therapeutics by Dr Petrie, on general pathology by Dr Golla and Mr C. Geary, and on pathological chemistry by Captain Mann. Dr Boud lectured on the legal relationships of insanity, Dr Shrubbsall on mental deficiency, and Dr East on criminal insanity. Dr Golla and Dr Walsh gave instruction on clinical neurology, and Mr Foster Moore on eva changes as applied to psychiatry. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas, for one single series of lectures in Part I the fee was 4 guineas and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S E 5.

BETHLEM ROYAL HOSPITAL

A course will be held at Bethlem Royal Hospital, commencing on September 24th, of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed in future to give two courses each year—an autumn session of intensive character, commencing in September, and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts. Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology, Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy of the nervous system, a series of lectures, with clinical demonstrations, on different branches of psychological medicine, and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas max, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable post-graduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the Physician-Superintendent, Bethlem Royal Hospital, S E 1.

NATIONAL HOSPITAL, QUEEN'S SQUARE

Post graduate courses which fulfil the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases are held at the National Hospital, Queen's Square, Bloomsbury, W C 1, three annually, usually during February to March, May to June, and October to November. Lectures on the pathology of the nervous system and various clinical lectures are delivered and demonstrations are given. Out-patient clinics are held at the hospital on the afternoons of Mondays, Tuesdays, Thursdays and Fridays. An entrance fee of 9 guineas is charged for the whole course, but any part of the course can be taken separately at a special fee. A special arrangement is made for those unable to attend the whole course and for details applications should be made to the dean of the medical school. Fees are payable to the secretary of the hospital on entering for the course.

TAVISTOCK SQUARE CLINIC FOR FUNCTIONAL NERVOUS DISORDERS

Courses in the theory and practice of modern psychotherapy are held at this clinic about twice a year. Each course lasts a fortnight, and consists of about twenty lectures and ten seminars. These courses are intended for general practitioners interested in the subject and as an introduction for those who mean to specialize. They are open to senior students of medicine as well as to graduates. The subjects dealt with include the various schools of analytical psychology, treatment by persuasion and suggestion, differential diagnosis, and physical factors. Syllabus and particulars of dates and fees may be obtained from the Honorary Lecturo Secretary at 51, Tavistock Square, London, W C 1. Clinical assistantships are from time to time available for graduates who have attended such a course. The director of the clinic is Dr H Crichton Miller, the deputy director Dr J R Rees, and there is a children's department under the directorship of Dr W A Potts.

THE PUBLIC HEALTH MEDICAL SERVICES

The central authority to secure the adoption, effective carrying out, and co-ordination of measures conducive to the health of the people, and to promote research work and the proper training of persons for health services, is the Ministry of Health.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs, and urban and rural sanitary districts. The administrative County of London, exclusive of the City of London, is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services, and, in addition, a large number who give part-time services. The medical officers appointed for these services may be either medical officers of the Ministry of Health for England or of the corresponding Boards of Health for Scotland and Wales, or—and these form the large majority—there may be medical officers appointed by the many local public health authorities. These latter appointments include medical officers of health, tuberculosis medical officers, maternity and child welfare medical officers, venereal diseases medical officers, and school medical officers—who must be regarded as working in the health interests of the school child. By the larger public health authorities assistant medical officers are also appointed, and these posts often serve as stepping-stones to the higher offices as vacancies, which are required to be advertised, occur.

THE MEDICAL SERVICES OF THE CENTRAL AUTHORITY

The Medical Department of the Ministry of Health for England has been organized under the control of a chief medical officer. It contains six sections, with a senior medical officer at the head of each, and about fifty medical officers. The sections deal with general health and epidemiology, maternity and child welfare, tuberculosis and venereal diseases, the supervision of food supplies, and sanitary administration in relation to infectious diseases. There is, in addition, a section concerned with insurance practitioners. Appointments to these posts are not as a rule open to public competition, they are made by the Minister of Health. They are civil service appointments, and come under the civil service superannuation scheme. Medical officers are also employed by the corresponding Boards of Health for Scotland and Wales.

MEDICAL OFFICERS OF HEALTH

The duties of the medical officer of health is to inform himself upon all influences affecting, or threatening to affect, injuriously the public health within his district, to advise his sanitary authority upon all matters relating to health, and to perform all the duties imposed upon him by statutes, by-laws, and regulations. He must prepare and submit to his local authority special and annual reports,

give in immediate information to the Ministry of Health of any serious outbreak of disease, and, subject to the instruction of his sanitary authority, he shall direct or superintend the work of sanitary inspection.

By the Sanitary Officers Order, 1926, no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualifications prescribed by any statute, he is also either registered in the *Medical Register* as the holder of a Diploma in Public Health, Sanitary Science, or State Medicine, or has had not less than three years' previous experience of the duties of a medical officer of health.

The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales, a part of whose salary is contributed by the Exchequer, shall not be appointed for a limited period, and shall not be removed from his office except by or with the consent of the Minister of Health. A similar security of tenure also applies to the medical officers of health of county councils and of London boroughs.

Under the Sanitary Officers Order, 1926, a medical officer of health who does not devote his whole time to the duties of his office, but a portion of whose salary is obtained from a reliever grant, may be appointed without limit of time, in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation Act, 1922. Under this Act if an officer is incapacitated by ill health after ten years of service, or if he has reached 65 years of age, he is entitled to superannuation on the following scale after ten years' service, 10/60 of the average salary which he received during the last five years of employment, after eleven years, 11/60, and so on up to a maximum of 40/60 after forty years or more of service. This Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officers, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which the British Medical Association has been working for many years.

In Scotland the position is different in some respects. The central authority is the Board of Health, with a staff of medical officers for insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

SCHOOL MEDICAL OFFICERS

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform their parents of its existence. Most approved schemes of medical inspection include arrangements which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of this treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain ameliorative work, notably the prescription of glasses where necessary, dental treatment, the removal of adenoids and tonsils, and treatment in

connexion with certain diseases of the skin, and some physical and mental defects. The general object of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing the development of conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, as a rule, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A Diploma in Public Health is almost always required of those entering the school medical service.

In Scotland, while the statutory authority for the work of the school medical service is different, the scheme of work is broadly the same.

TUBERCULOSIS MEDICAL OFFICERS

A tuberculosis medical officer is a whole-time officer with special training and experience in tuberculosis work, and of a suitable age and attainments to command general confidence. In England and Wales such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of diagnosis of tuberculosis, to advise as to treatment, and to take charge of the work of tuberculosis dispensaries and sanatoriums where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar.

MATERNITY AND CHILD WELFARE MEDICAL OFFICERS

Any public health local authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are embraced in county council schemes. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties, but for the larger schemes special whole-time appointments are made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitations, and the whole of this work is closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations, some of it still remains in their hands, and is only loosely linked up with the public health local authority, but the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts during recent years.

VENEREAL DISEASES

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the whole-time public health staff, and in others he is a part-time official. Special knowledge and practical experience in the treatment of venereal diseases are essential. The officer appointed for either whole-time or part-time service works at one or more clinics, and also gives instructions and assistance in the treatment of venereal diseases to general practitioners, who are allowed to attend the clinics.

REMUNERATION FOR SERVICES

In order to ensure that public health authorities may obtain skilled and highly trained medical officers, it is essential that such officers should receive salaries commensurate with their attainments, bearing a reasonable relationship to the time and money expended in fitting them for their important and responsible duties, and comparing well with the income which might be secured in other lines of medical work. With this end in view the Association and the Society of Medical Officers of Health, in November, 1918, commenced the preparation of a scale of minimum commencing salaries for whole-time public health medical officers.

The scale, which was put into operation in 1925, has the approval of the Ministry of Health, and is now applied to England and in Northern Ireland and in Scotland (with modifications). The salaries laid down in this scale are briefly as follows:

Resident Medical Officers at hospitals, sanatoriums etc. without responsibility for the work of other medical officers £350 a year *plus* emoluments.

Medical Officers employed in departments, working under a senior medical officer and without responsibility for the work of other medical officers £600 a year.

Senior Medical Officers (not medical officers of health) in charge of services or departments £750 to £1100 according to responsibility and scope of department.

Deputy or Chief Assistant Medical Officers (hospitals, sanatoriums etc.) A salary equal to 60 per cent of the salary of the medical superintendent or senior medical officer in charge.

Medical Officers of Health. The salaries are graded according to population from £800 to £1,800.

During the three years this scale has been in operation it has been adopted in respect of a steadily increasing number of appointments made. During the last twelve months it has been adopted in respect of 87 per cent of the whole-time public health appointments which have been filled.

For the right class of practitioners with leanings in the direction of public health work the service offers a successful career, but it must always be remembered that there are comparatively few posts which carry the higher salaries.

THE REGULATIONS FOR THE DIPLOMA IN PUBLIC HEALTH

The Examination

By the Regulations or Rules of the General Medical Council, which came into force on January 1st, 1924, the examination for the D.P.H. is divided into two parts, and no candidate is allowed to sit for the final part of the examination until two years have elapsed since a registrable qualification was obtained. The object of this two years' interval is "to provide opportunity for candidates for the Diploma or Degree in Sanitary Science, Public Health, or State Medicine to pass from the state of pupilage to that of responsible practitioners, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity either in practice or in hospital or laboratory appointments."

The examination is both written and oral and must include practical examination in bacteriology and chemistry (Part I) and in infectious diseases, food inspection, inspection of premises, dwellings, factories, workshops, schools, etc. (Part II).

Any candidate from the Dominions who possesses qualifications registrable in this country is eligible as a candidate for the examination, given that he has received such a course of training as that defined by the Regulations, at an institution which is approved by the General Medical Council.

The Curriculum for the Diploma in Public Health

The curriculum must extend over a period of twelve months, and a candidate is admitted to either part of the examination after he has completed the prescribed course of instruction in the subjects thereof. At least five months must be given to practical laboratory instruction in an institution approved by the licensing body in the subjects:

- (1) Bacteriology and parasitology including entomology especially in relation to diseases of man and to those diseases transmissible to man from the lower animals (180 hours of such instruction is required).
- (2) Chemistry and physics in relation to public health (90 hours of such instruction is required).
- (3) Microbiology and climatology (10 hours of such instruction is required).

Therefore at least 280 hours of practical instruction, extending over a period of at least five months, is demanded before a candidate is eligible for Part I of the examination.

For a candidate to become eligible for Part II of the examination he must first receive instruction in:

- (1) Principles of public health and sanitation (for approximately 30 hours).
- (2) Epidemiology and vital statistics (approximately 20 hours).
- (3) Sanitary law and administration including public medical services (approximately 20 hours).
- (4) Sanitary construction and planning (approximately 10 hours).
- (5) Every candidate must also have made thirty attendances of

not less than two hours in each week of a three months period at the clinical practice of a recognized hospital for infectious diseases and he must have received instruction in methods of administration

(6) Every candidate must produce evidence that he has during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of public health administration under the supervision of a medical officer of health, who shall certify that the candidate has received, from this officer or other competent medical officer during not less than three hours on each of sixty working days practical instruction in these duties and those relating to

- (a) Maternity and child welfare service
- (b) Health service for children of school age,
- (c) Venereal diseases service,
- (d) Tuberculosis service
- (e) Industrial hygiene
- (f) Inspection and control of food including meat and milk

Certificates of having received the prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work or by the medical officer of health of a sanitary area having a population of not less than 50,000 or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000

TRAINING AND EXAMINING CENTRES FOR PUBLIC HEALTH QUALIFICATIONS

Degrees in Sanitary Science are conferred, in England, by the Universities of London, Durham, Liverpool, and Birmingham, in Scotland, by the Universities of Glasgow and Edinburgh, and in Ireland, by the University Colleges of Dublin and Cork. In most cases these degrees are conferred only upon medical graduates of the universities granting them.

Whereas for the Diploma of Public Health the requirements of the General Medical Council are strictly conforming to, these requirements are extended, as a rule, as to both the period and the scope of special studies demanded, before Degrees in Sanitary Science are granted.

Almost all the universities of Great Britain and Ireland grant a D.P.H. and provide for the necessary training. The English and Scottish Conjoint Boards and the Irish Colleges also grant these diplomas.

In London at the present time there are fewer training centres for the D.P.H. than formerly, but candidates who desire to train in London can do so at University College and the Royal Institute of Public Health, and also at the Medical Schools of St George's and Middlesex Hospitals when a sufficient number of candidates apply for the training. It is expected that by October of next year all the post-graduate teaching and training in public health, in London, will be provided at one centre only—the London School of Hygiene and Tropical Medicine, which is in process of erection.

The Royal Naval Medical College and the Royal Army Medical College provide courses of training to the medical officers of these two services.

Degrees and Diplomas in Public Health are registrable qualifications, but not so those in Tropical Medicine and Hygiene.

QUALIFICATIONS IN TROPICAL MEDICINE AND HYGIENE

The University of London grants a degree (M.D. in Tropical Medicine) to their medical graduates, and the course of training required must extend over at least one academic year.

Diplomas in Tropical Medicine and Hygiene are granted, in England, by the Universities of Cambridge and Liverpool, and by the English Conjoint Board, and, in Scotland, by the University of Edinburgh. Among the institutions which provide qualifying courses are the London School of Hygiene and Tropical Medicine, the Liverpool School of Tropical Medicine, and the Royal Army Medical College. In the last-mentioned institution the training provided is restricted to army medical officers. The training period for these diplomas is about six months. Graduates of medicine and surgery of recognized universities whose degrees are not registrable in this country may enter for the examination of the English Conjoint Board, and the conditions of study may be modified on the grounds of previous work in the tropics or of original investigations undertaken.

The Colonial Office has decreed recently that the holder of a D.T.M. and H., or of a D.T.H., is eligible for appointment as a medical officer of health in places and districts other than those with large populations. In the latter cases a D.P.H. is required.

Those wishing for the details of syllabus of study, fees, date of commencement of the training courses, and the dates of examinations, etc., of any particular training course or examining body, will find these fully and clearly set out, with notes and comments, in the *Guide to the Regulations, Courses and Examinations for Qualifications in Public Health and Tropical Medicine and Hygiene in Great Britain and Ireland*, which has been prepared recently by Dr. Andrew Balfour, C.B., C.M.G., D.P.H., and published by the British Medical Association (Tavistock Square, W.C.1). The price is 3s. net.

The University of Manchester has a well-equipped department of bacteriology and preventive medicine, where candidates preparing for the examinations of the various university and examining boards for the Diploma in Public Health can obtain instruction. It also prepares candidates for the Diploma in Bacteriology and in Veterinary State Medicine, granted by the university, and for its Certificates in Factory Hygiene and School Hygiene. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester.

The University of Edinburgh grants a Diploma in Public Health. The course, which extends over a period of twelve calendar months, can be commenced in October only, and provision is made by the university for instruction in all the subjects. Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or must hold corresponding degrees or registrable medical qualifications, which must be registered before a candidate is admitted to examination. The course for the diploma is divided into two parts, for each of which examinations are held twice annually—in March and July for Part I, and in October and March for Part II. In each part the candidate must pass in all the specified subjects at one examination. Admission to the examinations is contingent upon the candidate having complied with the following conditions:

PART I—(a) Completion subsequent to obtaining a registrable medical qualification of the course of instruction prescribed for Part I.

PART II—(b) Completion subsequent to obtaining a registrable medical qualification of the course of instruction prescribed for Part II. (c) A lapse of two years after obtaining a registrable medical qualification. (d) Previous passage of examination in all subjects of Part I.

Further particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

THE NAVY, ARMY, AIR FORCE, AND INDIAN MEDICAL SERVICES

THE Medical Departments of the Royal Navy, of the Army, and the Indian Government normally employed between them before the war some 3,000 medical men and vacancies in the ranks of these services were filled by offering commissions for competition once or more each year. In the abnormal circumstances arising out of the war and the period following it the usual regulations for recruiting the permanent medical staff of these services were, for the most part, in abeyance, and the newly formed Royal Air Force Medical Service also has depended largely upon short service commissions for the maintenance of its medical personnel.

Meanwhile recruitment for the Royal Naval Medical Service and for the Royal Army Medical Corps was seriously prejudiced by disadvantageous terms and conditions of service. Continued representations were made by the British Medical Association, and, largely as a result of its action, substantial increases in the rates of pay and retiring gratuities, and improved conditions of retirement for officers of the Royal Army Medical Corps were embodied in a Royal Warrant issued by the War Office on June 29th, 1926. In securing these improved terms the Association gained a very notable success.

Simultaneously the Air Ministry announced improvements in the conditions of service and the emoluments of medical officers of the Royal Air Force. The Admiralty also issued an Admiralty Fleet Order prescribing improved terms and conditions of service for medical officers R N. The changes, generally, took effect from July 1st, 1926.

The British Medical Association, after examination of the revised terms, is satisfied with the new rates of pay and conditions of service for the R N M S, the R A M C, and the R A F M S, and in fulfilment of its desire to assist in recruiting these services we publish below full particulars.

There still appears to be considerable difficulty in getting a sufficient number of young medical officers to enter any of these services, and the Association desires to point out that in its opinion the prospects in them are both financially and professionally good, and that there is no reason why young men recently qualified should not enter them. In the case of the R A M C the prospects of rapid promotion are particularly good, owing to the prolonged shortage of candidates since the war. Another important point should be noted—namely, the concession by which a newly qualified medical man can hold a hospital appointment for one year before entering the services, counting it as a year of service towards promotion and retirement.

Indian Medical Service

The Indian Medical Service at one time afforded exceptional prospects, but great changes have now ensued following upon the reforms in India. Recently the Secretary of State announced the terms on which the I M S would be reorganized, and particulars of these changes will be found at page 421. The British Medical Association is convinced that the new proposals will not attract an adequate number of European medical men so long as

(a) the posts of Chief Administrative Medical Officers of Local Governments are not specifically included in the list of appointments reserved for officers of the I M S, and

(b) the prospect of employment on the civil side, which was one of the strong inducements to young graduates to enter the service, is as indefinite as it is at present,

and has so informed the India Office.

ROYAL NAVAL MEDICAL SERVICE

An Admiralty Fleet Order, issued in July, 1926, announced changes in the terms and conditions of service for naval medical officers. The improvements include an increase in the establishment of Surgeon Captains from 16 to 20, and also in the number and remuneration of specialist appointments open to medical officers. The total number of these appointments is 60. They comprise specialist posts in medicine, surgery, radiology, and hygiene, and the allowance payable to holders of them has been raised from 2s 6d to 5s a day.

Courses of instruction in clinical medicine, surgery, and allied subjects are normally provided once in every four years for all officers below the rank of Surgeon Captain, and on completion of the courses officers will be appointed to a large naval hospital unless and until they receive appointments elsewhere. Courses in connexion with civil hospitals in London or other teaching centres are also arranged at intervals for those selected to hold specialist appointments.

Medical officers entering the Navy will be eligible, at the discretion of the Admiralty, to have their seniority antedated up to a limit of one year if they have held previously a resident appointment in a civil hospital for not less than this period. Such an appointment must be one recognized by the Admiralty for this purpose, and must not have terminated more than six months before entry into the service.

Examinations for direct entry into the Medical Service are at present in abeyance. Entries are made by means of the short-service scheme.

General Conditions as to the Short Service Scheme

A candidate must be registered, must be under 30 years of age, and must be recommended by the dean of his school, if however,

the candidate intends to apply for transfer to the permanent list, he must have been under 28 years of age at the time of his entry. He must be a British subject of pure European descent. Unmarried candidates will be preferred. A candidate will be interviewed by the Medical Director-General R N and will undergo a physical examination. If considered eligible by the Medical Director-General his name will be submitted to the Board of Admiralty, and he may be appointed surgeon lieutenant for short service. A candidate must engage for three years, with the option of continuing for a further period of twelve months if his services are still required. The present rate of pay is £1 4s 10d a day or £453 4s 2d a year, with the same allowances as are payable to permanent officers of their rank. Lodging money at the rate of £20 a year is usually allowed when employed on shore, without quarters in the United Kingdom and £56 10s a year in lieu of rations when not victualled in kind. On joining an allowance of £50 for uniform is made.

An officer engaged for three years is entitled to receive two months' notice of his services being no longer required. A gratuity of £8 6s 8d will be payable to officers for each completed month of service on completion of their period of service or to any who are invalided for causes not within their own control before the completion of the prescribed period.

Transfer to Permanent Service

A short-service surgeon lieutenant, after six months' service, may be considered, on application to the Secretary of the Admiralty for transfer to the permanent service and would be permitted to count his seniority from the date of entry for short service for purposes of promotion, increment of full pay and for retired pay, but for purposes of retiring gratuity on the permanent officers' scale his service will reckon only from the date of transfer to the permanent list.

Officers entered for short service who are eligible for the grant of increased seniority in respect of time served in civil hospital appointments will only be allowed the antedate of seniority if they apply to transfer to the permanent list within eighteen months of their date of entry.

Rates of Pay

The current rates of full pay and retired pay are set out below. They represent a deduction of 6 per cent from the standard rates which were fixed in 1920 when the cost of living was high. 20 per cent of the standard rate is regarded as variable as the cost of living rises or falls. The next revision will be on July 1st, 1930.

Full Pay

	Current Rate per annum.
Surgeon Lieutenant on entry	£ 410 12 6
After 3 years	438 15 8
(Surgeon Lieutenants usually receive promotion after 6 years' service)	
Surgeon Lieutenant Commander on promotion	599 4 2
After 3 years	635 14 2
(Surgeon Lieutenant Commanders usually receive promotion after 12 years' total service)	
Surgeon Commander on promotion	772 11 8
After 3 years	839 10 0
After 6 years	909 9 2
After 9 years	976 7 6
Surgeon Captain on promotion (promotion is by selection)	1,116 5 10
After 3 years	1,201 9 2
After 6 years	1,285 12 6
Surgeon Rear Admiral (promotion is by selection)	1,780 13 0
Medical Director-General (Surgeon Vice-Admiral)	2,350 0 0

There are also allowances which form a substantial addition to the rates of pay.

Medical officers in charge of naval hospitals and sick quarters receive charge pay on the following scale:

Surgeon Rear Admirals and Surgeon Captains	10s a day
Surgeon Commanders	5s a day

Maximum Retired Pay (Approximate current rates)

	£	Age for compulsory retirement
Surgeon Vice Admiral	1,125	On vacating office
Surgeon Rear Admiral	950	60
Surgeon Captain	836	55
Surgeon Commander	554	50
Surgeon Lieutenant Commander and Surgeon Lieutenant	423	45

Thus an officer who is not promoted above the rank of Surgeon Commander would be compulsorily retired at the age of 50.

Gratuities on Retirement

The following gratuities are payable if an officer of the permanent list is permitted to retire voluntarily.

	£
After 4 years full pay service	500
8	1,000
12	1,500
16	2,250

Surgeon Lieutenants for short service transferred to the permanent list will only be allowed to retire with a gratuity after four years' full pay service from the date of such transfer.

Further Particulars

Full particulars and a form of declaration can be obtained from the Medical Director-General, Admiralty, Queen Anne's Chambers, Tothill Street, London, S W 1.

ARMY MEDICAL SERVICE

ENTRANCE to the Royal Army Medical Corps, either by competitive examination or by selection, as decided by the Army Council, will take place half-yearly, in January and July. The examinations in medicine and surgery are entirely of a clinical and practical character, partly written and partly oral. The regulations for admission, giving full details, can be obtained from the Under Secretary of State (A M D 1) War Office, Whitehall, London, S W 1. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable. The rates of pay and allowances are good, the opportunities of post-graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer, should he so desire, to leave the service with a capital sum large enough to go a long way towards re-establishing himself in civil life, and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the army will be of no small value to him.

New entrants who must be 22 and not over 28 years of age are commissioned in the rank of lieutenant and the first six months of service are spent on probation during which time they undergo in addition to their military training at the Royal Army Medical Corps School of Instruction at Aldershot a probationary course at the Royal Army Medical College in London in hygiene pathology tropical medicine military surgery organization of military hospitals and principles governing medical charge of troops. At the end of this course and after qualifying at the necessary examinations their commissions are confirmed and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers Training Corps service with possession of certificate A or B (medical) carry a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination a resident house appointment at an approved civil hospital may be seconded while holding such an appointment up to a maximum period of twelve months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to twelve months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period.

After a total period of one year's service at home the young officer goes abroad probably to India for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene. His tour abroad lasts five years with probably six months leave home during that time. On returning home the R A M C officer has the opportunity to decide whether he will remain in the corps or accept the gratuity of £1,000 after seven years' service and try his fortune in civil life. If he elects to remain he will between his eighth and twelfth year of service undergo a course of post-graduate study at the Royal Army Medical College and the London hospitals of five months' duration, followed by a course of study of a special subject selected by himself provided he has shown special aptitude

in the post-graduate course or during his previous service. During this period of study he remains on full pay and the fees of the courses are paid by the State. When qualified in his special subject the officer is eligible for a specialist appointment. The total number of these appointments is 104 and the additional rate of pay 4s 8d a day. After this post-graduate course the officer probably proceeds abroad again and promotion to major rapidly ensues and from that time onward he receives regular successive increases of pay and is eligible for additional and charge pay as well. The directorates of hygiene and pathology and the appointment of two serving officers as consultants in medicine and surgery have been instituted, and have proved a marked success. All these appointments are of the rank of colonel or major-general, and were devised to permit specially selected officers to rise through all ranks to that of major-general on the strength of their professional or purely scientific work.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There is scope for original research in tropical disease, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in medicine, surgery, or gynaecology, in venereal disease, and in ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps. At the same time, instruction in administration is continuous. There are also many appointments carrying administrative responsibility to those officers who display capacity for this duty.

Promotion

Promotion takes place automatically to captain after three and a half years' and to major after twelve years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

Pay and Allowances

The rates of pay and allowances are given in the accompanying table (see below). In addition an officer at home in charge of a hospital receives charge pay, the daily amounts being from 2s 6d to 10s, according to the number of beds. There are other appointments for which charge pay is given from 5s to 10s daily.

Retirement and Retired Pay

Retired pay will consist of two parts: (a) a service element based on the officer's total service; (b) a rank element for the rank from which the officer retires. An officer with less than twenty complete years' service will not be eligible for retired pay. The scale subject to the reduction of 6 per cent. referred

Pay and Allowances at Home

Rank	Pay per Diem *	Rations †	Servant	Married			Unmarried.		Total per annum	
				Lodging	Fuel and Light (Average)	Furniture Allowance	Lodging	Fuel and Light (Average)	Married	Unmarried

Major-General	4 9 4	1 7	4 0	11 0	5 2	2 0	11 0	3 8	2064 0 0	2000 0 0

Pay Warrant rates less 6 per cent. from July 1st 1927. The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision may take place with effect from July 1st 1930.

† Rates of Allowances vary from time to time.

Rates of Pay for Officers Serving in India

Rank.	Rates of Pay per Month						
	Unmarried			Married			
	Pay of Rank	Unmarried Rates of Lodging Allowance	Total	Pay of Rank	Married Rates of Lodging Allowance	Marriage Allowance	Total
	Rupees	Rupees	Rupees	Rupees	Rupees	Rupees	Rupees
Lieutenant	625	25	£50	625	50	65	*740
Captain	755	45	£60	755	90	100	*945
Captain after 8 years service ...	850	45	£65	860	90	100	£1050
Captain after 10 years service ..	930	45	975	930	90	100	1120
Major	1070	55	1125	1070	110	90	1270
Major after 15 years service ..	1170	55	1225	1170	110	90	1370
Major after 18 years service ..	1370	55	1375	1320	110	90	573
Major after 20 years service ..	1420	55	1475	1420	110	90	1610
Lieutenant-Colonel	1575	75	1650	1575	150	75	1800
Lieutenant-Colonel after 3 years service	1750	75	1825	1750	150	75	575

* Married rate of pay is not admissible to officers whose age is under 33

to below is, for the service element, £15 a year for each completed year of service as a medical officer. For the rank element the scale is as follows:

Rank from which Retired	After Completing 1 Year's Service in the Rank.	After Completing each Additional Year's Service	Maximum Rank
Major	£12	£12	£120
Lieutenant-Colonel	150	30	240
Colonel	290	50	390
Major-General	440	50	540
Lieutenant-General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

The maximum rates of retired pay are as follows:

Captain and Subaltern	£300
Major	£450
Lieutenant-Colonel	1600
Colonel	1800
Major-General	£1,000
Lieutenant-General	£1,200

The above rates are those laid down in the Pay Warrant. They have been reduced by 6 per cent. as from July 1st 1927. Further revision may take place triennially to an extent not exceeding 20 per cent. according to variation in the cost of living.

Officers with seven and less than twenty years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale:

After 7 years' service as a medical officer	£1,000
After 3 years' service as a medical officer in the rank of major	£2,800
After 6 years' service as a medical officer in the rank of major	£3,600

Seconded Service

An officer may be permitted to accept employment in the Foreign or Colonial Offices when so seconded he is not eligible for pay or allowances from army funds but his service continues to reckon towards promotion and under certain conditions towards increase of pay, pension, or gratuity.

Service on the West Coast of Africa

Officers for service in West Africa are usually taken from a list of volunteers for such service. An officer at present receives, while actually serving in West Africa (which service may include ordinary leave not exceeding sixty-one days in a year, and any time spent at Madeira or the Canary Islands on sick leave), additional pay at the following daily rates: Lieutenant-colonel 12s., major 9s., captain 7s. 6d., lieutenant 6s. Service on the West Coast of Africa also counts double towards voluntary retirement and the service element of retired pay under certain conditions, and also entitles to leave at home of one day for every two days' service after twelve months' continuous service on the coast. Continuous service includes the ordinary sixty-one days' leave and any time spent in Madeira or the Canary Islands on sick leave for this purpose.

THE ARMY DENTAL CORPS.

The corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force, and the personnel is required to serve under either force and be interchangeable. The regulations for admission to the Army Dental Corps should be obtained from the Under-Secretary of State, War Office.

ROYAL AIR FORCE MEDICAL BRANCH

THE Air Council attaches great importance to attracting into the R.A.F.M.S. the best type of medical man, since on the capacity of the medical service depends in a peculiar degree the safety and efficiency of the Royal Air Force. The duties of these medical officers include, not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration. The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook, who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation. His duties will be a matter of course, give him flying experience as a passenger which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

Commissions

The establishment will consist partly of permanent and partly of short service officers.

An officer will, on first entry, be granted a short service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council, if the officer so wishes on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

For those entrants who desire it, the prospect of obtaining a permanent commission is approximately an even one. Experience has so far shown that the officers selected have included the great majority of those desirous of and suitable for retention in the service, owing to the fact that the short service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, or who, on entry, have not made up their minds to the adoption of a permanent career in the service and subsequently find that they would prefer to return to civil life.

Medical officers may be allowed to count as service their time spent in resident appointments in civil hospitals under the following conditions:

(1) An officer granted a short-service commission who at the time of application for the commission holds, or is about to hold, a resident appointment in a recognized civil hospital, may be seconded for the period not exceeding one year from the date when the commission is granted, during which the appointment is held. If the applicant already holds the appointment when the commission is granted the commission may be antedated to the date on which the appointment was first held, provided (a) that the appointment is held for not less than one year, (b) that the period of secondment and the period of antedate shall not together exceed one year and (c) that the antedate shall not be made until the officer has joined for actual R.A.F. duty.

(2) An officer granted a short-service commission who has previously held a resident appointment in a recognized civil hospital for a period not less than one year may provided the commission is granted not more than six months after the termination of the hospital appointment, be granted an antedate of the commission equal to the period of the appointment up to a maximum of one year.

(3) The term "resident appointment" as used at (1) and (2) may be held to include a period of not more than six months in a non-resident appointment immediately preceding or following a resident appointment, provided the interval between the two appointments does not exceed three months.

(4) If necessary, the ordinary maximum age for appointment to a commission may be increased by a period equal to any antedate granted under (1) and (2).

(5) An officer who has been seconded or whose commission has been antedated as above will be required to serve for a minimum period of three years on the active list from the date of joining for actual R.A.F. duty.

(6) Pay and allowances for periods of secondment or antedate will not be allowable and such periods will not be reckoned in the assessment of gratuities payable to short-service officers. Subject to (5) however such periods will be reckoned as commissioned service in the Royal Air Force for purposes of seniority and promotion and in the case of permanent officers of retirement retired pay and retirement gratuities.

Officers who have been selected for permanent commissions

may be permitted to attend for a period not exceeding nine months a post graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted at any time when the exigencies of the service permit during the first sixteen years of service, and when attending these courses officers will receive full pay and allowances.

New entrants into the R.A.F.M.S. will be commissioned as Flying Officers (Medical), and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after sixteen years total service, and to that of Group Captain by selection at any period after twenty-two years service.

There will be no competitive examination on entry, candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, and will be interviewed by a Selection Board at the Air Ministry, London, presided over by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce

- 1 Birth certificate
- 2 Medical registration certificate
- 3 A declaration containing the following information:
 - (a) Age and place of birth.
 - (b) That he is a British subject the son of British subjects and of pure European descent.
 - (c) That he is ready to engage for general service at home or abroad as required.
 - (d) The qualifications he is possessed of and what medical or other appointments he has held (if any).
 - (e) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course, during which they will be given instruction in the special medical aspects of aviation, the organization and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch. In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorized from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations and personal attendances are not available in kind. Normally provision in kind is available for junior officers. Married rates of allowances are payable only to married officers who have reached the age of 35 or the rank of squadron leader. A colonial allowance is granted in certain commands abroad.

The rates and general scheme of allowances are liable to revision as circumstances may require.

Uniform and Equipment

Medical officers are required to provide themselves with the uniform, service dress, and mess dress of their rank, and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H M Forces.

Pay and Allowances

The emoluments of medical officers of the Royal Air Force are given in outline on page 420. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent of each of the standard rates is detachable and subject to alteration, either upwards or downwards, as the cost of living rises or falls. Under this provision the current rates now in force represent a reduction of approximately 6 per cent on the standard rates. The next revision will take effect from July 1st, 1930, and subsequent revisions will be made at intervals of three years.

Retired Pay

The minimum period of service qualifying for retirement on retired pay is twenty years. Standard rates of retired pay are as follows:

Air Officer—Air Vice Marshal, £790 to £1,010 per annum, Air Commodore, £650 to £950 per annum.

RETIRED PAY (PERMANENT OFFICERS) Officers Below Air Rank

Age on Retirement	Standard Yearly Rate of Retired Pay	Years of Service	Addition for each Extra Year of Service *	Deduction for each Deficient Year of Service *
40	£ 300	17	£ 15	£ 15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15
47	562	20	15	15
48	600	21	15	15
49	637	21	15	15
50	675	22	15	15
51	697	22	22	15
52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

Limited to five years

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are

Rank.	Yearly Rate of Retired Pay	Compulsory Retiring Age
Air Vice-Marshal	£ 1010	60
Air Commodore	950	57
Group Captain	900	55
Wing Commander	600	51
Squadron Leader	500	48

Gratuities

A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service—namely, £1,500 if he has ten but less than fifteen years' commissioned service, £2,500 after fifteen or more than fifteen years.

Short service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service; £150 for each of the third and fourth complete years, and £200 for the fifth complete year, that is, for three years' service on the active list £350, for five years £700.

These gratuities will not be payable to officers granted permanent commissions, but their service on a short service commission will count towards retired pay.

Further particulars may be obtained on application to the Secretary, Air Ministry (D M S.), Adastral House, Kingsway, W. C. 2.

INDIAN MEDICAL SERVICE

In May, 1928, the Secretary of State for India issued a communiqué announcing the terms on which the Indian Medical Service would in future be constituted. The communiqué was to the effect:

(i) That the I M S. constituted on the same broad lines as at present will be retained primarily to meet the needs of the Indian Army, the Local Governments being required to employ a stated number of I M S. officers in order to maintain the necessary minimum war reserve and to provide for European medical attendance for European officers of the I C S. and their families.

(ii) That the total number of I M S. officers required for civil employment is calculated at 302 of which 212 will be Europeans and 90 Indians.

(iii) That there will be 237 posts for these officers after allowing for leave and study reserve 178 of which will be in the provinces and 59 under the Government of India.

These posts will be filled as follows:

Under Provincial Governments 178 posts, of which 112 must be held by European officers, the remaining 66 to be open to Europeans or Indians.

Under Government of India 59 posts, of which 28 will be open to Europeans or Indians, the remaining 31 being open to Europeans only.

(iv) That the medical requirements of European members of the Superior Civil Services are based on data which will change from year to year as the proportion of European to Indian officers gradually diminishes and will be subject therefore to periodical revision.

(v) That certain rules will come into force as an integral portion of the scheme. These rules deal with the question of employment on the military and civil side and provide *inter alia* that liability to serve on either the military or civil side will be a definite condition of service for all future entrants to the Service.

The civil appointments which are reserved for officers of the I M S., and which exclude the posts of Chief Administrative Medical Officers of Local Governments, are scheduled in the communiqué.

European candidates for admission to the I M S. must be British subjects under 32 years of age, and must be registered under the Medical Acts in Great Britain and Northern Ireland. A gratuity of £1,000 on retirement after six years' service, or £2,500 after twelve years' service, together with free return passages, is offered.

The Indian Medical Service offers wide opportunities of medical experience, including clinical preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major General. After two years' Indian service an officer may apply for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes, to specialist (for example, public health and bacteriological) services, to research posts, and to professorships at the Medical Schools. It must be understood, however, that opportunities for employment on the civil side are indefinite.

The monthly rates of pay for European officers in the Service who have a "non Asiatic" domicile are as follows:

Rank.	Service in Rank	Basic Pay	Overseas Pay	Year of Total Service
1	2	3	4	5
Lieutenant		Rs 500	Rs 150	1st
Captain	(i) During first 3 years service as Captain	650	150	2nd
	(ii) With more than 3 and less than 6 years service as Captain	750	150	3rd
	(iii) With more than 6 years service as Captain	850	150	4th
Major	(i) During first 3 years service as Major	950	150	5th
	(ii) With more than 3 and less than 6 years service as Major	1100	150	6th
	(iii) With more than 6 years service as Major	1250	150	7th
Lieut.-Col.	(i) Until completion of 23 years total service	1500	150	8th
	(ii) During 24th and 25th years total service	1600	150	9th
	(iii) After completion of 25 years total service	1700	150	10th
	(iv) When selected for increased pay	1850	150	11th
				12th

Extras—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

Officers on appointment will receive an outfit allowance of £50. With the exception of Administrative Officers military or civil and officers holding certain special appointments officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

The rates of pension are as follows.

	Per annum.
After 17 years service for pension	£400
" 18 " " "	430
" 19 " " "	460
" 20 " " "	500
" 21 " " "	540
" 22 " " "	580
" 23 " " "	620
" 24 " " "	660
" 25 " " "	700
" 26 " " "	750
" 27 " " "	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent in all, the revision being undertaken triennially with effect from July 1st, 1927. A reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot lasting approximately six months, prior to their embarkation for India on first appointment.

Further particulars may be obtained from the Under Secretary of State for India, Military Department, India Office, London, S W 1

PRISON MEDICAL SERVICE

CANDIDATES for the prison medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Mr. M. L. Waller, C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S W 1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

In February, 1923, the then Home Secretary appointed a committee to report on what changes, if any, should be made in the remuneration or other conditions of service of officers at the prisons and Borstal institutions in England and Scotland and at Broadmoor Criminal Lunatic Asylum. Evidence was given on behalf of the British Medical Association by the Medical Secretary, who pointed out that the salary offered to Class II medical officers—namely, a basic salary of £300 rising by annual increments—was, even when the allowances and bonus were reckoned in, less than the £500 a year the Association looked upon as the minimum commencing salary which should be given to a whole-time medical man holding such a responsible office. Following the report of the committee, which was issued in November, 1923, the salaries of whole-time prison medical officers were increased to Medical officer Class II, £350, rising by annual increments of £20 to £600, medical officer Class I, £650, rising by annual increments of £25 to £800. Unfurnished quarters are provided, or an allowance in lieu is made. The civil service bonus is paid on the salary. There are 15 medical officers Class II, 12 medical officers Class I, and 23 part-time medical officers.

The service is a small one, and therefore vacancies are comparatively rare and promotion is very slow.

POOR LAW MEDICAL SERVICES

A NUMBER of whole-time appointments exist under the various Poor Law authorities in Great Britain, certain of which, notably in the metropolis and the chief provincial cities, maintain large well-equipped hospitals organized under purely medical administration. Posts are available to medical practitioners as superintendents and assis-

tant officers in hospitals and infirmaries, and as resident officers in other institutions, such as poorhouses, workhouses, etc. Conditions and salaries show considerable variation, salaries for resident assistant medical officers in Poor Law infirmaries usually range from £200 to £450 a year, with full board, the duties being much the same as, but as a whole more responsible than, those of a house-physician or house surgeon in a general hospital. Medical superintendents are paid from £600 to £1,600 a year, with house, light, coal, laundry, etc., and in some cases the first assistant is termed deputy medical superintendent and receives £450 to £750 a year, with similar emoluments. This service, therefore, offers openings for young practitioners and the prospect of a reasonable degree of progress for those who may choose to make it their career, with security of tenure, and provision for superannuation. It should be added that the attractiveness or otherwise of any particular post is affected considerably by the policy adopted by the authority under whose jurisdiction it falls. In the more advanced areas there is a high degree of differentiation in treatment between the sick and mentally affected, and the purely pauper class (between the hospital and the workhouse), the tendency in such areas has been to develop the hospital services on lines approximating to those ruling in the voluntary hospitals. In the smaller unions, however, lay control, through the administration by a workhouse master of the whole organization, has been preserved, and medical appointments in such circumstances are less attractive. A considerable change in administrative conditions in the Poor Law in England and Wales may be expected in the near future, as it is the intention of the present Government to introduce legislation which will involve, among other things, the abolition of the boards of guardians, and the transfer of their functions to larger units. This should result in greater uniformity in conditions, and probably in a higher degree of specialization in Poor Law work, particularly on the medical side, and a closer assimilation to other public health services. In addition to the full-time appointments of the character mentioned, the Poor Law service offers numerous part-time posts, such as those of district medical officer, parish medical officer, public vaccinator, etc., which are practically all held by general practitioners.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are generally admissible merely on payment of a registration fee, providing they produce evidence that they are of good reputation and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has in the past been established between this country and all the provinces of Canada except British Columbia, where certain obstacles were never overcome. It has, however, to be recorded that reciprocity with Saskatchewan, New Brunswick, Ontario, and Quebec has recently been brought to an end by those provinces. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register. The Licence of the Dominion Council, which can only be obtained after examination, entitles its holder to practise in any of the provinces of Canada, though in regard to Quebec there is a proviso that "he must have been registered in the province five years prior to the application for the recognition of the Dominion Licence." In order to sit for the examination for the Dominion Licence, it is necessary to obtain a licence from one of the provinces, but this can be obtained from one of those with whom reciprocity has been established.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established, though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice, and all of them require the holder of a British qualification to submit to an examination. The States of New York and Indiana require naturalization.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s 6d, or 2s 9d post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. A new edition was published last year.

MEDICAL APPOINTMENTS IN THE COLONIES AND MANDATED TERRITORIES

MEDICAL appointments in the self governing Dominions and the territories under their control, and in Southern Rhodesia, are made by the Governments concerned, and are not in general open to candidates in the United Kingdom. Appointments to the medical services of the colonies and other territories under the administrative direction of the Colonial Office are, apart from those in Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, Bermuda, and Malta, which are filled locally, made by the Secretary of State for the Colonies in this country. Such appointments are to a given colony or colonies, for there is no unified service directly administered from the Colonial Office. It follows that conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local Government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always either up to date or complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions, and particularly as to facilities for private practice where this is included in the terms of appointment. He will also do well to supplement official information by reference to the central office of the British Medical Association, where reports obtained from time to time from the local Branches are available. This is the more necessary because facilities for transfer from the Medical Service of one colony to that of another are as yet practically non-existent, except in connexion with a few specialist and senior appointments, thus sets strict limits upon the opportunities for promotion.

To those physically and mentally suited for the climatic and social conditions peculiar to the various colonies the Colonial Medical Services should, and in some cases do, offer a field of professional activity rich in interest and in opportunity for pioneer work. The scope for research is wide, and facilities for its prosecution are beginning, however tardily to be provided. An increasing number of specialist posts is becoming available in the larger services, and the general policy is to fill them by promotion of suitably qualified junior officers. The potentialities of sanitation are beginning to be appreciated by local administrations, however vaguely. But, when all is said, it cannot be contended that conditions in the Colonial Medical Services are generally satisfactory. In some instances indeed, they can only be characterized as intolerable. Hence the necessity for very full inquiry before accepting appointment. It is true that the post-war economic straits to which the delay of essential reform was usually attributed is giving place to more favourable conditions. There are also signs of increasing parliamentary and departmental interest in

the development of a sound health policy. Amongst these the most significant is perhaps the recent appointment by the Secretary of State, in consultation with the Medical Research Council, of a Committee "to advise the Secretary of State and the Medical Research Council upon the initiation and promotion of medical research in the interests of the Colonial Empire, upon the recruitment and conditions of service of the necessary personnel, and upon the management and allocation of any funds available for these purposes." The appointment of a chief medical adviser to the Secretary of State for the Colonies has also had its effect. We are confident that the work of this officer will contribute greatly to the establishment of conditions making for efficiency and well being in the Colonial Medical Services. Meanwhile, those services are too often hampered by conditions which make efficiency unattainable. At the worst they are in some colonies starved of material resources in the name of economy, understaffed, and underpaid, with inadequate facilities for study leave and at the mercy of an administration in which the nominal head of the service has no effective voice. Hence the urgent necessity for making careful and sufficient inquiry as to the position in any given service before appointment is accepted.

The medical services recruited in this country by the Secretary of State for the Colonies include those of West Africa, East Africa, Malaya, Hong Kong, the West Indies, Fiji, and Western Pacific territories, and Palestine, besides a number of small services offering individually one or two appointments at an inadequate remuneration and with no prospects of promotion. The recent revision of the conditions of the Fiji Medical Service shows a distinct improvement in this colony. The basic salary of the district medical officers is £500 by £25 to £725, and although this is below the £600 minimum recommended as adequate by the British Medical Association this fact is offset by the concession of allowances of from £175 to £275 in five of the districts, the value of private practice in the remaining seven being estimated at from £200 to £600 a year. During the last twelve months improvements have been effected in the conditions of service in Hong-Kong, the Western Pacific, and the Bahamas. The services in the West Indies and some of the smaller colonies have not yet conceded the £600 minimum commencing salary, and whilst facilities for remunerative private practice, general conditions of service, and a relatively low cost of living must in some instances be taken into consideration, these compensations are by no means universal. The services in the Leeward and Windward Islands are in a condition which requires special notice by way of warning.

In general candidates for these services must be between the ages of 23 and 35, although these limits are not for the moment absolute. A candidate over 35 years of age, if accepted for appointment, may be required to serve on a temporary and non-pensionable footing, regular appointments are, subject to a varying period of probation, for the most part classed as permanent and pensionable. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the Consulting Physicians to the Colonial Office. Post-graduate experience in hospital appointments is desirable and in some cases special allowances are conceded to the holders of a D.P.H. Successful candidates for the West African Medical Staff, the East African Medical Service, and the Malayan Services are normally required to undergo an approved course of instruction in tropical medicine, the fees for their tuition being defrayed by the Government and an allowance being paid during their instruction.

The bulk of the appointments made by the Secretary of State in this country are to the West African Medical Staff, the East African Medical Service, and the Medical Services in Malaya. These are the strongest individual services numerically, and therefore offer more frequent vacancies, better prospects of promotion, and better chances of specialist appointments than the smaller services.

WEST AFRICAN MEDICAL STAFF

This is amongst the best organized and best paid of the Colonial Services though at present it appears to be understaffed. The territories covered by the service include

Nigeria, the Gold Coast, Sierra Leone, and the Gambia. Climatic conditions vary considerably over this area but they are in general admittedly trying. This fact is at present recognized by the provision of more frequent leave periods than are usual elsewhere.

The rate of pay for a medical officer is £660 on appointment, rising by annual increments to £860, together with a seniority allowance of £72 a year after reaching £720. There are a considerable number of specialist and administrative posts carrying relatively high salaries, varying from £1,300, with duty allowance of £250, to £1,800, with duty allowance of £360. All appointments in the staff are pensionable. Officers may retire voluntarily on reaching 50 years of age, and may be called upon to retire at 55. Pensions are calculated at the rate of 1/480th of the officer's pensionable emoluments (salary and house allowance) in respect of each complete month of service. Alternatively a gratuity and reduced pension may be granted, if desired, under certain conditions. Gratuities of £1,000 or £1,250 may be drawn on retirement after nine or twelve years' service. Members of the West African Medical Staff are not usually permitted to take their wives or young children to the West Coast until they have acquired experience of the conditions of life and have obtained the sanction of the Governor. In the case of young children this is only exceptionally given.

African Medical Officers

In addition to members of the West African Medical Staff which is limited to British subjects of European parentage there are a number of Government appointments for African medical officers in the West African Colonies. These appointments carry salary on the scale £500-£25-£600 and there is a higher scale £600-£250-£720. In addition in Nigeria and the Gold Coast arrangements have been made for the employment of a few young African medical men temporarily on the hospital staffs, with a view to appointment to the Government service later if suitable. In such cases a salary of £400 a year is paid.

EAST AFRICAN MEDICAL SERVICE

This service includes Kenya, Uganda, Tanganyika Territory, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is a very wide scope for clinical work, both medical and surgical, as well as for research and for preventive medicine and sanitation. The service as a whole is fully alive to its responsibilities and opportunities. Individual initiative is encouraged, and the career of a medical officer depends, not on seniority alone, but to a large extent on his own capability. As a rule it is preferable that medical officers on first appointment should not be married although in all but a few stations conditions allow a medical officer's wife to accompany him. The service includes a medical and a sanitary division. The former is open to those holding ordinary medical and surgical qualifications, post graduate experience in a hospital appointment being an advantage, posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health. Climatic conditions vary considerably. In a considerable part of Kenya they approximate more to the temperate than the tropical zone, but there are some areas in the East African Dependencies where conditions more closely resemble those in West Africa. The rate of pay for a medical officer is from £600 on appointment rising by annual increments of £30 to £840, and thereafter, subject to an efficiency bar at this point, by £40 to £920. Holders of the D.P.H. receive a special concession of two increments on appointment, thus reaching the maximum of the grade two years earlier than they would otherwise do. Private practice may be permitted in certain circumstances, but there is no right to it even in stations where opportunities may exist.

Whilst a candidate can only apply for appointment to the East African Medical Service in general and is liable to transfer between the several dependencies, he may express his preference for any particular colony and his wishes will be met as far as possible. As a rule transfer only takes place on promotion or at an officer's own request. The gratuities available on retirement after nine or twelve years' service are similar to those for the West African Medical Staff. Officers may elect or may be required to retire on pension on reaching the age of 50 years. Pensions are calculated at the rate of

1/480th of emoluments (including value of free quarters) for each completed month of service.

MEDICAL SERVICES IN MALAYA

These services cover the Straits Settlements, the Federated Malay States, and some of the unfederated States. Certain reforms have recently been effected in the Malayan Services, and whilst that in the Federated Malay States still suffers from the inclusion of the Medical Department in the general decentralization of administration carried out since the war, the new commencing salary of 500 dollars a month plus an allowance of 10 per cent for single and 20 per cent for married officers, is generally considered adequate. A non-pensionable allowance of 100 dollars a month is paid to officers holding the Diploma in Public Health. The service should now offer considerable scope to suitable candidates.

SUDAN MEDICAL SERVICE

This service is a department of the Sudan Government, and includes a number of Syrian medical officers and a number of assistant medical officers who are natives of the Sudan. The British medical inspectors are from the outset senior to all other medical officers. The Sudan is entering on a period of rapid development and expansion, to which the medical services of the country must necessarily make an important contribution. The service offers ample opportunities for specialization and for research, as well as for general medical and surgical work. The ordinary duties of a medical inspector may be summarized as follows:

- (1) To act as a consulting surgeon and obstetrician in all cases submitted to him by his medical staff. This necessitates considerable surgical experience.
- (2) To initiate, organize, and supervise all medical and sanitary work in his province. This includes extensive antimalarial work and often the supervision of large irrigated areas.
- (3) To carry out the medical supervision of schools and the examination of candidates for Government service and pension.
- (4) To train assistant medical officers and native sanitary overseers, and to advise and direct medical officers in the carrying out of their duties.
- (5) Probably, at a later date, to take part in teaching at the School of Medicine at Khartoum.

The climate varies, but is not in general unfavourable, though hot. In the northern desert the nights are cool even in the summer, in the central there is a rainy season of about four months, during which large areas become malarious. The southern area is more tropical in character, and mosquito-protected houses, nets, and protective quinine are essential during the greater part of the year, though the winter months are cool and pleasant. It is not considered desirable for medical inspectors to be accompanied by their wives until they have gained some knowledge of the language and the general conditions of life.

The commencing pay of a medical inspector is £E 720*. On confirmation of appointment and success in the requisite examinations in Arabic the salary is increased by periodic increments to £E 1,200. There are four senior administrative posts carrying higher salaries. There is a compulsory contribution of 5 per cent of pay towards pension, which, for a medical inspector, amounts, after twenty years' service to £E 500 a year.

PALESTINE

A few of the senior posts in the Health Department of the Government of Palestine are recruited in this country. The scales of pay vary between £P 550-£25-£750+ with expatriation allowance of £P 100 for an assistant senior medical officer and £P 1,200 with an expatriation allowance of £P 200 for the director.

OFFICIAL SOURCES OF INFORMATION

All inquiries in connexion with medical appointments in the self-governing Dominions and their dependencies should be addressed to the High Commissioners or Agents-General.

£E = £1 0s 6d sterling. This figure represents exchange value not purchasing power.
£P = £1 0s 6d sterling. This figure represents exchange value not purchasing power.

for the Dominions. Intending applicants are also recommended to consult the Colonial Office List, which may be seen at the Colonial Office Library or at the central office of the British Medical Association if not otherwise available, and the Professional Handbook (price 9d) issued by the Overseas Settlement Office, Caxton House, Tothill Street, London, S W 1.

Recent developments seem to suggest the possibility of a few appointments becoming available under the Egyptian Government. Questions about any such appointments should be addressed to the Director-General, Public Health Department, Cairo.

Inquiries as to vacancies and conditions in the Sudan Medical Service should be addressed in the first instance to Dr T D Acland, 19, Bryanston Square, London, W 1.

All inquiries in connexion with Colonial medical appointments made by the Secretary of State for the Colonies, or such vacancies as may occur in Iraq or Palestine, should be addressed to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S W 1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Medical Secretary's Department of the British Medical Association, British Medical Association House, Tavistock Square, London, W C 1.

DEGREES FOR PRACTITIONERS

At one time it was the almost universal custom for medical students educated in London and aiming at general practice not to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted that the M D Brux diploma, if obtained subsequently to June, 1886, is not registrable, and that the University of Brussels no longer holds special examinations for foreign medical practitioners.

UNIVERSITY OF DURHAM

The degree of M D is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions, without residence. The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previous to the professional examination in virtue of which his name was placed on the Register, he is examined in classics and mathematics, if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books), Virgil, *Aeneid* (first three books), or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain, and must be registered on the books of the General Medical Council of the United Kingdom.

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics, (ii) principles and practice of surgery, (iii) midwifery and diseases of women and children, (iv) pathology, medical and surgical, (v) anatomy, medical and surgical, (vi) medical jurisprudence and toxicology. Candidates are examined by means of written papers, clinically, and *viva voce* at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s) of the full fee.

The examinations are held twice a year, in June and December. Notice, accompanied by the fee and certificates,

must be sent to the Secretary of Examinations, at the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

Fees.—The fee is 50 guineas which includes the degree fee if a candidate fail to pass, 20 guineas are retained, but if he present himself again 40 guineas only are required.

THE SWISS UNIVERSITIES

The Universities of Lausanne and Berne have arrangements which permit British practitioners to proceed to the M D degree, but this alone does not confer the right to practise in Switzerland, for which the possession of the State or Federal Diploma is necessary. Neither degree is registrable in this country.

At Lausanne the British practitioner has to produce (1) a certificate of matriculation in a British university or of having passed a preliminary examination recognized by the General Medical Council for the purposes of registration as a medical student, (2) a certificate of a degree or diploma qualifying for practice in the United Kingdom and the certificate of registration as a medical practitioner in the United Kingdom. He must then undergo a *viva voce* examination in three subjects of the final medical examination. Next he must present a thesis for the doctorate prepared and completed in one of the Lausanne clinics under the direction of one of the professors of the Faculty of Medicine. Residence for a semester (October to March or April to July) is obligatory. The fees are on matriculation 20 francs on inscription for the *viva voce* examination 50 francs on presentation of thesis 200 francs for diploma and graduation 25 francs for courses of lectures and laboratory instruction 80 francs the printing of the thesis costs from £7 to £12. Applications for admission should be made to the Dean of the Medical Faculty Ecole de Médecine Place de l'Our Lausanne. An official publication (*Guide de l'Étudiant*) is issued in October and April and may be obtained (price 50 centimes) from M. F. Haeskel Dufey 3 Rue Centrale Lausanne. Dr C A H Franklin (58 Southborough Road Bickley Kent) honorary secretary of the Lausanne Medical Graduates, will supply further information.

MEDICAL RADIOLOGY AND ELECTROLOGY

THE CAMBRIDGE DIPLOMA

A DIPLOMA in Medical Radiology and Electrology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The diploma is open only to those who hold a medical qualification approved by the Diploma Committee.

Under the new regulations, which come into operation in October, 1928, the course has been extended from six to nine months. The first three months (October to December), which may be spent either in Cambridge or in London, are occupied with lectures and practical work in physics and electrotechnics, together with an introductory course in medical radiology and electrology. The work for the second three months (January to March) can be done in London only, and comprises lectures and clinical instruction in radiology and electrology given by lecturers appointed by the Educational Committee of the British Institute of Radiology, together with clinical experience in the radiological department of a hospital recognized for that purpose by the Diploma Committee. During the last three months a candidate is required to hold a clinical clerkship, or other similar appointment, in the radiological department of a recognized hospital. Hospitals at a number of provincial centres, as well as in London have been recognized by the Committee for this purpose. In exceptional circumstances exemption from this regulation may be granted by the Committee.

The examination for Part I (physics and electrotechnics) is normally taken at the end of the first three months, and the examination for Part II at the end of six months. At the conclusion of the nine months' course a candidate is required to present a thesis composed by himself. This thesis is to be in the form of a critical report with notes upon six cases either in radiology or electrology or in both these subjects and must illustrate various methods of diagnosis or treatment.

Further particulars of the courses and examinations can be obtained from G. Stead M A, Cavendish Laboratory, Cambridge, or from the Director, British Institute of Radiology, 32, Welbeck Street, London, W 1.

THE EDINBURGH DIPLOMA

Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the examination.

The course of study begins in October and extends over a period of not less than three terms. The examination, which is written, oral, and practical, is in two parts: (a) physics, and (b) radiology. The examination is held twice yearly—namely, July and October. Full particulars may be obtained from the Dean of the Faculty of Medicine.

THE LIVERPOOL DIPLOMA

The University of Liverpool grants a Diploma in Medicine, Radiology and Electrology. Candidates before admission to the examination for the diploma must possess a registrable qualification approved by the university in medicine and surgery, and must have attended courses of instruction in (a) physics (two terms), (b) (1) radiology and (2) electrology, during six months in the x-ray and electro-therapeutic departments of a hospital or hospitals. An examination is held in March each year, the subjects being (a) physics, (b) radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £24 5s., examination and diploma, £6 5s. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

MEDICAL MISSIONARIES

Missionary societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the secretaries of the various Missionary Societies, or from Thomas Cochran, M.B., C.M., Honorary Secretary, British Advisory Board on Medical Missions, 1, Tudor Street, London E.C.4.

Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments corresponding very closely with those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely the reservation of the use of certain titles. This Act provided also (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner" or any other name, title, or

description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20, and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry; hence, unqualified practice was far more prevalent in dentistry than in medicine, and increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

THE DENTISTS ACT, 1921

This unsatisfactory position was remedied by the passing into law of the Dentists Act, 1921, its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered dentist is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic, further, any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Certain persons other than those qualified by examination were entitled to be registered under the new Act. They had to be of good personal character and 23 years of age before July 28th 1921 (the commencement of the Act) and to have been engaged for five of the seven years preceding that date as their principal means of livelihood in the practice of dentistry in the British Isles or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of the prescribed examination in dentistry within two years of the commencement of the Act was considered as equivalent to practising for five years and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist including all dental operations was treated as though he had practised for five years. A dental mechanic who for the five years had been carrying on his work as such and has secured the entry of his name on the list of candidates for examination can be registered provided within ten years of the commencement of the Act he passes the prescribed examination. The Board however has no power now to consider any further applications under this Act.

Dentistry may be carried on by a corporate body provided the majority of the directors and all the operating staff are registered dentists and that no business other than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions provided that the name of the company as well as the names of the directors have been entered in a list kept by the Registrar for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge and the court may in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

A subsequent Act passed in 1923 made provision for the registration of persons who were 21 in November 1921 who had served during the late war in His Majesty's Forces, and were on that

date engaged as their principal means of livelihood in the practice of dentistry in the British Isles. The Board, however, has no power now to consider any further applications under this Act.

THE DENTAL BOARD

On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* is made by the Board, which reports its findings to the General Medical Council, the order directing the erasure being made by the Council. A name erased from the *Register* can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hallam Street, London, W 1.

DENTAL EDUCATION AND EXAMINATION

The preliminary examination in arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects¹, and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the commencement of professional education, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Degrees in dentistry are granted by the Universities of Bristol, Durham, Leeds, Liverpool, London, Sheffield, Queen's University, Belfast, and the National University of Ireland, as will be found stated in the articles on these universities. Licences in dentistry entitling the holder to be registered on the *Dentists Register* are granted by the Universities of Birmingham, Bristol, Durham, Leeds, and Belfast and by the Royal Colleges of Surgeons of England, of Edinburgh, and of Ireland, and by the Royal Faculty of Physicians and Surgeons of Glasgow.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square, the National Dental Hospital (now the University College Hospital Dental School), Great Portland Street, Guy's Hospital, King's College Hospital, and the London Hospital. In the provinces there are the Birmingham Dental Hospital, the Royal Infirmary and the General Hospital, Bristol, the Dental Hospital and the Public Dispensary, Leeds, the Dental Hospital, Liverpool, the Dental Hospital, Manchester, the Dental Hospital and School, Newcastle-on-Tyne, the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee, the Incorporated Dental Hospital and School, Edinburgh, and the Incorporated Dental Hospital, Glasgow, and in Ireland, the Incorporated Dental Hospital of Ireland and the Royal College of Surgeons in Ireland.

A list of dental schools and their officials will be found in the article on the General Medical Council at page 377.

All who think of becoming dentists may be advised to study a Memorandum, lately drawn up for their guidance by the Registrar of the Dental Board, setting out in convenient form and in untechnical language information for which request is frequently made to the Board.² It will be seen from this pamphlet that in order to assist suitable students the Dental Board has instituted a system of bursaries to pay the fees of those who have not the financial means to qualify, and in some cases maintenance is given as well.

Recommendations of the General Medical Council

The *Dentists Act* still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council on May 27th, 1922.

¹ See the Registrar's Memorandum on Students' Registration printed in the article on the General Medical Council at page 376.

² Memorandum by the Registrar on the Procedure to be Adopted by Those who Desire to Enter the Profession of Dentistry with Notes on Costs and Prospects. 1927. Dental Board of the United Kingdom. 44 Hallam Street, W 1. Price 1s. post free.

Preliminary Examination and Registration

1 That every dental student shall, at the commencement of his student ship, be registered in the manner and under the conditions prescribed for medical students.

2 That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education which shall be the same as that required for medical students, an examination in Elementary Physics and Elementary Chemistry, conducted or recognized by one of the licensing bodies which shall also be the same as that required for medical students.

3 That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

Professional Study

4 That every candidate for a degree or licence in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing—

- (i) That he is at least 21 years of age.
- (ii) That he has been registered as a dental student.
- (iii) That he has subsequently to the date of registration as a dental student been engaged in professional study for at least four years of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.
- (iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction which shall be the same as those required for medical students in the following subjects: (a) Chemistry, and (b) Physics in their application to medicine; (c) Elementary Biology. That he has attended at a recognized medical school courses of instruction in the following subjects: (d) Human Anatomy (with dissections and demonstrations) for three academic terms; (e) Physiology (with laboratory instruction including Practical Histology) for two academic terms; (f) General Pathology (including Bacteriology) for two academic terms; (g) Medicine for two academic terms; (h) Surgery for two academic terms; (i) the practice of a recognized general hospital or hospitals of not less than eighty beds, with certified instruction in Clinical Medicine and Clinical Surgery for four academic terms.
- (v) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy and Physiology human and comparative. The course should comprise a minimum of twenty meetings of the class; (b) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class; (c) Dental Pathology and Surgery. The course should comprise a minimum of twenty meetings of the class; (d) Dental Medicine and Therapeutics. The course should comprise a minimum of sixteen meetings of the class; (e) Dental Metallurgy (with practical work and demonstration). The course should comprise a minimum of twenty meetings of the class; (f) Dental Mechanics (with practical work and demonstration). The course should comprise a minimum of twenty meetings and twenty demonstrations; (g) A course of instruction in the use of Anaesthetics, general and local, employed in dental practice; (h) A course of instruction in Radiology as applied to dentistry.
- (vi) That he has for at least twenty-four calendar months attended, during the ordinary academic terms, the practice of a recognized dental hospital or of the recognized dental department of a general hospital.
- (vii) That he has received for not less than twenty-four calendar months or for 2,000 hours practical instruction in dental mechanics.

Professional Examinations

5 That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly practical, and shall include the following subjects: (a) Chemistry, Physics, and Biology in their bearing on Medicine and Dentistry; (b) Human Anatomy and Physiology; (c) General Path and Surgery; (d) Dental A. Pathology, Medicine and Surgery (including Therapeutics and Dental Mechanics and Metallurgy); (e) Anaesthetics, general and local, employed in dental practice.

6 That the prescribed subjects of examination may be combined or distributed at the discretion of the licensing bodies, and may be taken at two or more successive stages during the course of professional study, provided that no candidate shall be admitted to any final examination in dental surgery and dental mechanics until he shall have completed the required four years' course of study.

ACKNOWLEDGEMENT

THE detailed information published in this Educational Number of the *British Medical Journal* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several public services, to all of whom we wish to acknowledge our indebtedness.

MEMBERSHIP of the Guild of St Luke is open to all students and practitioners of medicine—both men and women—who are members of the Church of England, the clergy of which are eligible as clerical associates. The Guild was started in London by a few medical students over sixty years ago, and there are also now in London a Women's Ward and a Students Branch, as well as a Midland Counties Ward and a Cambridge Ward. The Chapter of the Guild meets in each month of the academic year and a festival service is held annually at St Luke's tide, either at St Paul's or Westminster Abbey. This year the service will be at the Abbey. Particulars of the objects and activities of the Guild and forms of application for membership can be obtained from the Secretary of the Guild of St Luke, Room B B, King's College Strand, W C 2.

[The present issue being the Annual Educational Number, much current material is held over, and neither the Supplement nor the Epitome of Current Medical Literature is published this week.]

The British Medical Association:

ITS AIMS, WORK, AND CONSTITUTION

THE British Medical Association, as stated in our introductory article on the Profession of Medicine, was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To attain these objects it holds periodical meetings for the discussion both of medical and scientific subjects and of professional affairs; it publishes the *British Medical Journal*, it maintains a reference and lending library, it has instituted lectures, and scholarships and grants for research. It thus concerns itself with every side of medical work—science, clinical medicine, public health, and the material interests of professional life. The British Medical Association, with a membership now of more than 34,000, is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It has recently acquired a fine building in Tavistock Square, London, for its headquarters, providing ample accommodation for immediate needs and space for future developments. These premises, designed by Sir Edwin Lutyens, R.A., were formally opened in 1925 by His Majesty the King, Patron of the Association, and the beautiful wrought-iron gates erected as a memorial to the 574 members who fell in the war, by which the quadrangle is at present completed, were dedicated on that occasion by the Archbishop of Canterbury. The need for larger accommodation had become insistent owing to the remarkable growth in the central work of the Association during recent years, which had far outstripped the capacity of the premises in the Strand. Further extensions to the building in Tavistock Square are now in progress.

The British Medical Association House, Tavistock Square, London.

Constitution and Administration

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. The Divisions are arranged territorially, and number, in all, 286. For certain purposes of administration or of scientific and clinical work, the Divisions are combined into 25 Branches. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science Medico-Political, Ethical Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales, and for the working machinery of the Association such as the Organization Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is financed by the Association; it is the recognized executive and mouthpiece of the insurance practitioners of Great Britain.

Privileges of Members

A member of the Association has the right—

- 1 To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs
- 2 To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body, and also in the election of members of the Council
- 3 To receive by post the *British Medical Journal* published weekly, which gives a full record with commentary of progress in clinical and scientific medicine and of medico-political affairs throughout the British Empire
- 4 To receive the help and advice of the central office in any professional difficulty
- 5 To use the Library as a reading room and to borrow current medical or scientific books on payment of postage. Besides modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession, for the greater the membership and the funds the more

efficient and influential the organization. The Association during the past ninety-six years has been the direct means of benefiting every class of medical men and medical women. In asking for new members it looks not only to the older practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition of the work of the Association in improving the conditions under which they may hold appointments in the public services or in civil life. The Association's work for the Services is well known.

It feels a special responsibility towards those members of the profession who by reason of their position are precluded from taking common action, and recent events have proved again its capacity to further their interests.

Subscriptions and Applications for Membership

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the British Isles, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration, medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas. Concessions are made also to members (in the British Isles) of forty years' standing to members of ten years' standing who have retired from practice, to medical married couples residing together, and to whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions. A member elected after June 30th pays half the subscription for that year.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Medical Secretary, British Medical Association House, Tavistock Square, London W.C.1, the Scottish Medical Secretary, 7, Drumshugh Gardens, Edinburgh, or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

A Paper

OF

THE DIAGNOSIS AND TREATMENT OF SPINAL CORD TUMOURS

BY

DONALD J. ARMOUR, CMG, FRCS,

Senior Surgeon West London Hospital Surgeon, National Hospital for Nervous Diseases

In this discussion on the diagnosis and treatment of spinal cord tumours I will limit myself to the strict meaning of the term—namely, those tumours arising from the cord, from the nerve roots, or from the spinal meninges—and exclude those arising, primarily or secondarily, from the vertebral column and the soft tissues surrounding it. Exception will be made in the case of chondromata growing from an intervertebral disc.

Clinically, spinal cord tumours may be said to cause a paraplegia by compression, the nature of which cannot be revealed by x rays. It should be remembered, however, that tumours arising from nerves or nerve roots outside the spinal canal may extend into it through an intervertebral foramen, and, vice versa, one originating in the spinal canal may extend in the same way into the soft tissues surrounding the vertebral column. Moreover, a tumour may be both intradural and extradural, without any clear evidence as to its point of origin. More than three-fourths of spinal cord tumours are extramedullary, and less than one-fourth intramedullary. Of the extramedullary tumours, the intradural are more frequent than the extradural by three to one. Of intradural tumours, about two-thirds occupy a dorsal or dorso-lateral position and one-third a ventral or ventro-lateral position—a matter for rejoicing on the part of the surgeon.

SYMPTOMS

In the majority of cases of spinal cord tumour the onset of symptoms is slowly progressive, the course of the disease being slow and chronic. From the clinical standpoint it may be divided into three stages: (1) of root symptoms, usually unilateral, (2) of Brown Sequard paralysis, (3) of complete compression paraplegia, or bilateral paralysis. According to Starr, "a certain order is commonly observed in the symptoms"—namely: (1) Pain referred to the periphery, (2) Increase of reflex activity below the point of compression, (3) Paralysis—spastic paraplegia in extension, (4) Loss of sensibility, (5) Loss of reflex activity with flaccid paralysis.

The first symptom complained of by the patient is usually sensory, either pain or some form of paraesthesia. There are exceptions to this, but though at the onset some cases have no sensory symptoms, they usually appear later in the course of the disease. A few cases run a completely painless course. These were formerly supposed to be cases of medullary tumour, but it is now known that some are extramedullary.

Root pain, due to irritation—"the neuralgic stage"—is the most frequent early symptom. "There is no other disease which causes such definitely localized recurring and persistent pain" (Starr). It may be paroxysmal and remittent, showing marked variations in its severity, and is frequently aggravated by coughing and sneezing or by movements of the spine. The pain may appear suddenly, may persist for months or years, disappearing as symptoms of cord compression appear, or it may continue throughout the whole duration of the disease. The pain is referred to the course of the nerve involved, and may be thought to be due to innumerable conditions in various parts of the body or limbs.

Pain in the back may be an early symptom in spinal cord tumour, and may be the only one complained of for a very long period. This is especially true of lumbosacral and cauda equina tumours. Various postures may be assumed by the patient to get relief from the pain.

Bennett¹ has called attention to the fact that orthopaedic surgeons are frequently consulted by patients com-

plaining of local and referred pains in the region of the spine who have no bone lesion but a lesion of the cord. He records four cases of spinal cord tumour, all having shown symptoms that suggested osseous, muscular, and ligamentous changes rather than any neurological condition. They showed (1) variable pain in the spine and nerve roots, (2) extreme spasm of the erector spinae muscles, followed by lateral deformity of the spine, (3) extreme bilateral spasm of the hamstring group—all appearing long before any motor or sensory changes had occurred.

Pain, not radicular in character or distribution, may be complained of in a part of the body not supplied by the roots involved in the tumour. This pain is due to pressure on the sensory tracts of the cord. It may antedate any discoverable sensory or motor changes.

Paraesthesiae of various kinds—"pins and needles," numbness, a feeling of weight, tingling, cold—may be complained of. They may occur at the level of the tumour, due to root irritation, or above the level of the tumour, due to pressure from the held up cerebro-spinal fluid or to sympathetic involvement (Barre and Schrapf) or below the tumour level, due to irritation of sensory tracts in the cord. Elsberg says that a complaint of a feeling of coldness in the extremities is a regular symptom of high cervical tumours.

In the early stages of spinal tumour objective sensory changes are usually absent, though areas of hyperaesthesia may be found on careful search. Later, the cutaneous sensory disturbances will depend upon the amount of compression or destruction of the spinal tracts, and will vary with the site of the tumour and its relation to the cord. Elsberg calls attention to the frequent occurrence in extramedullary tumours of a certain amount of dissociation of sensations below the level of the tumour, while in intramedullary tumours, on the other hand, he frequently found that all types of sensation were equally involved, while typical dissociation was rarely seen. He points out, however, that unless there is a loss of all sensation below the segmental level, there is a striking difference between the sensory disturbances in extramedullary and intramedullary tumours. It is this that in extramedullary growths the maximum of sensory disturbance is in the most peripheral dermatomes and the minimum nearest the level of the lesion while in intramedullary growths the maximum of sensory disturbance is often at and below the segmental level.

Unless all cutaneous sensation has been lost, tactile sensation is usually less affected than pain and temperature, which are often equally diminished. But many variants of this occur. In tumours of the conus and cauda equina the sensory disturbances are usually bilateral and symmetrical, affecting all types of sensation to an equal degree.

Subjective motor disturbance, consisting of a complaint of weakness followed by stiffness, usually follows subjective sensory symptoms though very rarely the reverse occurs. These symptoms of weakness and stiffness are usually progressive, though cases are reported in which they have been remittent. In high tumours the order of limb involvement is almost always in regular sequence—namely homolateral upper limb, homolateral lower limb, contralateral lower limb, contralateral upper limb.

During the first or irritative stage, if the tumour involves an anterior root there should be motor excitement as shown by tremor, muscular tension, spasms or general tonic spasms. But by the time the patient comes under observation these are generally absent or soon masked or suppressed by a degenerative paralysis of the corresponding muscles, together with a diminished tendon reflex. Obvious wasting of the muscles concerned usually follows, and this whether the root or the anterior horn cells are suffering from pressure.

At first as the tumour lies on one side of the cord it pressure may cause a spinal hemiparesis the so-called Brown Sequard syndrome characterized by motor disturbances on the same side as the lesion and sensory changes on the opposite side. This is rarely seen however, in its complete form in tumour compression and soon passes into a paraparesis or paraplegia. Elsberg has described what

¹Read in opening a discussion in the Section of Surgery of the Annual Meeting of the British Medical Association Cardiff 1923.

he calls a "reversed" Brown-Séquard syndrome, in which the motor and sensory disturbances are opposite to those described. The explanation of this would appear to be the pushing of the cord over against the opposite side of the canal by the growing tumour.

As soon as the tumour begins to exert further pressure on the cord two sets of spinal symptoms begin to appear—namely, (1) direct spinal symptoms, due to compression or destruction of the segments on which or in which the tumour lies, (2) indirect spinal symptoms, due to pressure upon the long tracts traversing the segment affected. Thus the atrophy and paralysis of muscles, often with fibrillary twitchings, the segmental supply being known, with reaction of degeneration and loss of reflex activity in the muscle tendons, combined with muscular weakness and rigidity and increased reflex activity below the lesion, an extensor plantar response, with anaesthesia up to the level of the lesion, and probably loss of bladder and rectum control, constitute a condition of great diagnostic value.

In those cases not only does a minimal stimulus produce the corresponding reflex, but very often a number of other reflex contractions—the so-called "mass reflexes" described by Riddoch, and called by Babinski "defence reflexes." Usually sphincter disturbances do not appear until motor and sensory symptoms are well advanced, though they may be early in onset in intramedullary tumours. Bladder loss is usually the first to appear, and precedes the rectal loss by some time. Very often "imperative micturition" appears first, or hesitancy passes into retention, and retention into incontinence.

It is interesting to remember here that it has been shown by Riddoch and Puives-Stewart that the pathological effect of the actual pressure on the cord elements are extraordinarily limited, the neural processes of inflammation, softening, and degeneration being confined to the immediate site of the tumour, and that the widespread interference with cord function is due to vascular changes, setting up what they call anoxaemia. That this must be true is shown by the recovery which follows, often rapidly, upon the removal of a tumour which has caused very great narrowing and distortion of the cord.

Paraplegia in Flexion

This condition has been very fully worked out and described by Walshe. It follows most frequently upon paraplegia in extension, but in a certain number of cases the extension stage is very short and the paraplegia in flexion may appear to be the original condition. It is characterized by (1) Flexion of the different segments of the lower limbs upon each other (dorsal flexion of the foot, flexion of the leg on the thigh, and the thigh on the pelvis) (2) Absence of the usual exaggeration of tendon reflexes, which may be diminished, and in some cases even abolished (3) A well-marked exaggeration of the "flexion reflexes" (Sherrington) (4) The almost constant presence of involuntary muscular contractions. There are also found objective sensory disturbances with a definite fixed upper limit, but the dominant clinical feature is the very obvious exaggeration of the flexion reflexes.

The condition indicates a severe and localized compression of the cord, and, in cases of tumour, is an indication for immediate operation.

Varying Clinical Picture at Different Levels

At different levels of the cord certain additional symptoms may be added to the usual clinical picture, and may be of great localizing value. In high cervical tumours nystagmus is occasionally present, probably due to alterations in the cerebro-spinal fluid pressure. Bulbar symptoms are occasionally seen, due, according to Schlesinger, to oedema of the medulla. Cranial nerve symptoms are very rare indeed. Intense pain may radiate up the back of the neck and head, giving rise to the stiffly held head suggestive of caries, or to an appearance of spasmodic torticollis.

The involvement of the roots of the phrenic nerve in tumour cases may result in paralysis of one or other side of the diaphragm, which can be verified by a ray screening. C. P. Symonds has had recently under his care a most interesting case of tumour at the level of the third cervical segment, which commenced with persistent hiccup, lasting

for a long time before the gradual onset of a quadriplegia. I have not been able to find a similar case reported in the literature, and therefore, with Dr Symonds's permission, I will describe the symptoms very briefly.

The patient, a man aged 45, was admitted under Dr Symonds's care in December, 1927, on account of spastic quadriplegia and attacks of hiccup. Two years previously he had begun to suffer from attacks of hiccup lasting three or four days at a time and so severe that they disabled him for the time being. Shortly after this he experienced pains in the back of the neck and across both shoulders. Six months later he began to notice weakness of his lower limbs, and at the end of a further six months was helpless, invalid with weakness in all four extremities.

On admission the Wassermann reaction was negative both in blood and cerebro-spinal fluid. The lumbar fluid showed a moderate excess of protein with no cells. Examination showed a spastic weakness of all four extremities with a defect to temperature and pinprick extending up to the clavicles and including the upper limbs. The lower limbs showed increased tendon jerks and extensor planar responses. The abdominal reflexes were absent. The reflexes in the upper limbs were increased and on scratching the skin on the anterior or posterior surface of the trunk at the level of either axilla a brisk reflex contraction of the muscles of the appropriate shoulder girdle ensued, leading to retraction of the upper limb—the reflex described by Buzzard and Riddoch (*Brain* 1923, 397) as occurring in spastic quadriplegia.

Whilst under observation the patient had a severe attack of hiccup lasting for three or four days and nights, and leading to great exhaustion.

In the lower cervical lesions four root syndromes may occur—namely, (1) the upper, or Duchenne-Erb type (C5, C6, C7), (2) the middle type (C7), with paralysis and atrophy of the triceps, (3) the lower, or Aran-Duchenne type (C8, D1), (4) the combination of the last with oculopupillary symptoms, Dejerine-Klumpke type (C8, D1, D2). The oculopupillary symptoms (Claude Bernard-Horner syndrome) are myosis, ptosis, enophthalmos, with narrowing of the palpebral fissure, together with vasomotor effects, as shown by redness or pallor of the skin, with hyperidrosis or anidrosis. It is in tumours of the cervical region that one sees the picture of a true spinal hemiplegia, which, however, soon passes into a quadriplegia. Paralysis of the upper limb may be of a spastic or atrophic nature, or may combine these characteristics. The radicular type of degenerative paralysis may be very clearly marked.

Tumours situated in the lower dorsal region of the cord may give rise primarily to pain simulating intra-abdominal disease, and every conceivable abdominal operation has been performed in such cases, in the erroneous belief that one or other abdominal organ was at fault.

Tumours of the lumbar cord may show multiple root signs with atrophic paralysis, but in other cases pressure on the cord may cause the outstanding symptoms.

Tumours of the cauda equina give rise to intense pain which may be widespread, in the small of the back or over the sacrum, and which radiates down the back of the legs, into the region of the anus, bladder, perineum, and genitalia. These are cases which are usually treated for "sciatica" over long periods. Anaesthesia over the anogenital region, extending down over the tendo Achillis, with loss of the anal reflex and Achilles jerk, with bladder and rectal disturbances, make a very distinctive clinical picture. Trophic sores are peculiarly frequent in lumbosacral and cauda equina tumours, in marked contrast to those at higher levels of the cord.

A brief reference should be made to the so-called "atypical" clinical forms, or those cases which do not conform to the usual clinical picture produced by the presence of a spinal cord tumour. These are (1) those with purely medullary symptoms, (2) those with purely root symptoms, (3) those with multiple tumours, (4) those with symptoms referred chiefly to the vertebral column and the paravertebral muscles—"forme rachialgique" or "pseudo-pottique" of French neurologists.

In the purely medullary form there is found a paraplegia without any signs of root involvement, either subjective or objective. According to Frazier and Ellis this form occurs once in every fourteen cases, and to Foerster in more than one-half of the cases. It is undoubtedly of frequent occurrence. It is explained upon the assumption that the tumour occupies an interradianal position, or lies on the anterior aspect of the cord, is of small size, and attached to the dural sheath. According to Oppenheim it occurs with extradural tumours occupying an anterior position and of very soft consistence.

In the purely root form the symptoms are those of an ordinary neuralgia of varying distribution according to the site of the tumour. Attention should be directed to the obvious root limitation of the painful phenomena, to their persistence and long duration, and to the interference with the tendon or cutaneous reflexes at the corresponding level. In cases of neuralgia of long standing with recessions, and which resist all forms of medication lumbar puncture should be performed and the cerebrospinal fluid examined, and if confirmatory evidence is necessary, followed by the injection of lipiodol.

The diagnosis of multiple tumours—diffuse sarcomatosis, neurofibromatosis, diffuse gliomatosis—sometimes offers very great difficulties. They are to be suspected by the presence of two root syndromes clearly superimposed, which are accompanied by other symptoms of compression of the cord. There may be symptoms of a high compression with a root syndrome lower down, or the reverse, in which the root syndromes are very much higher than those of the cord compression. Clinically a diagnosis with localization of the highest tumour is usually made. Help may be obtained in these cases from the use of lipiodol.

The vertebral form is met with especially in tumours of root origin compressing the lower end of the cord or the roots of the cauda equina. It is marked by the intensity and diffuseness of the pain, which is referred to the paravertebral muscles and down the lower limbs. In an attempt to relieve the vertebral pain a secondary contracture—localized or diffuse—of the affected muscles is induced. It is when it is localized that a diagnosis of Pott's disease is so often made. In the case of tumour the pain has an intermittent evolution, often with prolonged remissions and the appearance of objective neurological signs is often slow. Again, the rigidity of the spine is not absolute, some slight movement of the spinous processes upon one another being obtained, and it is much more diffuse than that of Pott's disease. Moreover, the contracted muscles are excessively painful, and are tender to pressure.

DIFFERENTIAL DIAGNOSIS OF TUMOURS OF THE SPINAL CORD

There is no symptom which occurs exclusively with any one form of spinal tumour. The individual symptoms are essentially the same, and differ in sequence, duration and time of appearance according to the localization of the tumour.

As between extramedullary tumours the intradural occur more frequently than the extradural in the proportion of three to one. The extradural tumours grow, as a rule more quickly than the intradural, and hence with them, the course of the symptoms is often more rapid so that a short history is in favour of an extradural tumour rather than an intradural one.

Bony changes, as shown by the x rays are frequent in association with extradural tumours while they are rarely seen with intradural, except in the so-called giant tumours of the cauda equina, which may cause an enlargement of the vertebral canal. Sensitiveness to pressure over the vertebral column is more frequent with extradural tumours. Root pain is more often absent with extradural tumours, and the spinal cord symptoms associated with them tend at first to be vague and indefinite.

It is especially with extradural tumours that lumbar puncture may produce a sudden and marked increase in the subjective and objective symptoms though this is also true of intradural tumours attached to the dura. The cerebrospinal fluid does not show xanthochromia so often with extradural tumours, nor is its protein content ever so high. Greenfield says that a great excess of protein in the lumbar fluid, combined with a completely normal cisternal fluid, is in favour of an extradural rather than an intradural tumour. Moreover, with an osteoma or chordoma there may be no evidence of any subarachnoid block. According to Elsberg the so-called "reversed" Brown-Séquard syndrome—contralateral motor and homolateral sensory disturbances—are often seen with extradural tumours.

It is often difficult clinically to differentiate an intramedullary from an extramedullary tumour; the differences between the two are often misleading, and the diagnosis

of an intramedullary tumour may be one of probability rather than of certainty. As a rule, in intramedullary tumours the root pains are less frequent, though they may be present, the Brown-Séquard syndrome is rarer, and the paraplegia is less spastic. Moreover, nutritive phenomena are more frequent and may be of localizing value. A typical and clearly shown dissociated anaesthesia is greatly in favour of intramedullary tumour, although a more marked alteration in painful and thermal sensibility, as compared with other sensory disturbances, is not rare in extramedullary tumours.

In favour of a tumour being *extramedullary* rather than intramedullary, one may set forth the following points:

- 1 A prehistory stage of root pain the signs of irritation preceding those of destruction.
- 2 The slow but continuous development of symptoms showing alterations in motor and sensory function.
- 3 The motor and sensory symptoms while increasing in intensity, show a tendency to maintain a stationary localization. In other words the growth of the tumour tends to be in breadth rather than in length.
- 4 The persistence of a Brown-Séquard syndrome for a fairly long time.
- 5 A marked degree of spasticity which persists after the appearance of a complete paraplegia together with early and pronounced development of the reflexes of defence in the whole of the lower extremity, with Babinski's sign well marked.
- 6 Symptoms of motor root irritation—cramps, spasms, tremor, muscular tension—and absence, or only slight development of signs of atrophic degenerative paralysis.
- 7 Absence of trophic troubles in the soft tissues.
- 8 Changes in the cerebrospinal fluid included in the term localisation syndrome.

AIDS TO DIAGNOSIS AND A LEVEL LOCALIZATION

These may be considered under the following headings: (1) Combined cisternal and lumbar puncture. (2) Evidence of a different chemical composition of the two cerebrospinal fluids (cisternal and lumbar). (3) Pneumomycelography. (4) Cisternal injection of lipiodol.

The method of combined cisternal and lumbar puncture has been elaborated by Aver as a means of determining the presence or absence of spinal subarachnoid block. Queckenstedt in 1916 using lumbar puncture alone, showed that the pressure in the lumbar canal rose on compression of the jugular veins when there was no spinal block, but did not do so in the presence of an obstruction. This obstruction must however, be complete. Aver's method is based upon the facts that in the normal individual the cisternal and lumbar fluids are practically identical, their pressures are the same and oscillations due to coughing, sneezing, holding the breath, or to compression of the jugular veins are of similar range. Although diminished pressure below the block is usual, normal pressures are not uncommonly found with tumours causing only a partial block, and occasionally an increased pressure may be found. This last may be due to a valvular action of a tumour, extramedullary in position, allowing a downward but preventing an upward flow of the fluid. Exudation of serum from the distended spinal veins may be also a contributory factor.

Normally the total amount of protein in the cerebrospinal fluid is approximately 25 mg per 100 c.c. of fluid. In cases of spinal block this figure may be increased a hundredfold in the stagnant fluid below the block. In addition, there also accumulates an excess of other substances, such as mineral salts and glucose, while the engorgement of the spinal vessels leading to a state of increased meningeal permeability causes the spinal fluid gradually to approximate in chemical composition to the blood plasma. Consequently in the fluid we find elements derived from the blood stream which are normally absent—altered blood for example producing the characteristic yellow coloration known as xanthochromia whilst the presence of fibrinogen may cause the fluid to clot spontaneously in the test tube.

The outstanding features in the cerebrospinal fluid below an area of spinal compression are therefore: (1) xanthochromia (2) increase in the amount of protein, and (3) occasional spontaneous coagulation. These three conditions are sometimes spoken of collectively as the "localization syndrome." Occasionally a condition of spinal fluid stagnation is encountered in the fluid lying immediately above a block, as shown by increased protein

content, with or without xanthochromia. This is to be explained by a transudation into the fluid from engorged veins in the spinal canal. As between demonstrable block and increased protein content, there is no doubt that the latter is a more delicate indication of cord compression or meningeal involvement.

The replacement of the cerebro-spinal fluid by air by means of lumbar puncture was devised independently by Dandy, Bingle, and Wideroc. The procedure is briefly as follows. With the patient recumbent but at an angle of 50 to 60 degrees, 10 c.c.m. of cerebro-spinal fluid are withdrawn by lumbar puncture and an equal amount of air injected. In the absence of any spinal block the air passes at once into the cranial subarachnoid space, causing a fairly sharp pain, successively localized by the patient in different parts of the head. According to Dandy, so constant and characteristic is this pain that it can be taken as positive evidence of the absence of a complete spinal block. To the pain are sometimes added nausea and vomiting, a rise in temperature, and collapse. In the presence of a spinal block no such pain is complained of, and Dandy then advises the injection of as much air as the spinal canal will hold, in order to obtain the maximum effect of the air shadow for the x-ray localization of the site of the block. He finds a single stereoscopic plate, with the patient lying on the back and the rays passing straight through, gives the best result. The method is valueless in the cervical region when shadows, due to the tracheal air, obscure the picture.

The cisternal injection of lipiodol was introduced by Sicard and Forestier of Paris. Its technique is too well known to require description here. Passing over the symptoms which may arise as a result of the injection of the lipiodol, the question is how much reliance can be placed upon lipiodol localization. Can medullary compression be excluded with a negative lipiodol result? Assuredly not. There is no doubt that with small tumours, or in rare cases where narrowing of the cord results from destructive new growths, such negative results will occur. Again, cases occur in which the neurological and lipiodol levels do not correspond. In other words, there is a sensory lipiodol dissociation. In some cases the sensory level is the higher, and in others the lipiodol. In the one case the sensory lipiodol dissociation may be explained on the assumption that the higher sensory level is due to the pressure of the stagnant fluid above the tumour and a localized ischaemia of the cord. In the other the lipiodol may be held up by meningeal adhesions above a tumour, or, in meningitis serosa circumscripta, at the level higher than the place where actual compression of the cord begins.

Given a sharply marked sensory level, I much prefer to depend upon it alone and to operate without the use of lipiodol. It is in cases in which the sensory level is not sharp and well defined, but gradually fades away as one passes upwards, that the lipiodol has its greatest field of usefulness.

May I quote here from my Lettsoman Lectures the rules which I formulated regarding the use of lipiodol in the diagnosis and localization of spinal compression.

1 Its use should in no way usurp the place of careful and repeated systematic clinical examinations of the patient, especially with reference to a sensory level, combined with laboratory tests of the cerebro-spinal fluid. Recourse to it as a labour-saving device and a short cut to diagnosis and localization cannot be too strongly deprecated.

2 It should only be used after a subarachnoid block has been first demonstrated by the combined cisternal lumbar puncture method introduced by Ayer.

3 It should not be used unless the possible dangers and complications are outweighed by the more exact localization likely to be obtained.

4 Finally, in properly selected cases we have in lipiodol a definite aid in the study of spinal cord compression which, if used intelligently, will increase definitely our successful removal of spinal cord tumours at an earlier stage in the course of the disease, and thereby increase our percentage of cures and reduce our operative mortality.

TREATMENT

There is only one treatment for spinal cord tumours—namely, their removal by operation. This demands both a correct diagnosis and a precise level localization. These

can only be arrived at by a careful history and by repeated systematic clinical examinations of the patient, especially with reference to a sensory level, combined with laboratory tests of the cerebro-spinal fluid. In doubtful cases may be added such subsidiary aids as have been already alluded to.

The determination and locating of the spinous processes and their relation to the segments of the cord is all important. It is well known that the segments of the cord do not correspond to the similarly named vertebrae, and there is considerable variation in the relation between the two. A serviceable rule is that the lower cervical segments are each two vertebrae higher, the upper six dorsal three, and the lower six dorsal four, than the corresponding vertebrae. The lumbar segments correspond to the tenth and eleventh dorsal spines and the sacral to the twelfth dorsal and first lumbar. In order to locate a spinous process commence counting from some easily recognized landmark—for example, the seventh cervical or first dorsal spine—and count downwards to the desired spinous process, and then confirm this by counting upwards from the fourth lumbar spine, an easily recognized one. In very stout individuals it may be necessary to mark one spine with a small lead plate and then have the entire spine x-rayed in order to localize it accurately.

I have no experience of osteoplastic laminectomy, nor of hemilaminar or unilateral laminectomy. Apart from the fact that osteoplastic operations are more difficult and take a longer time, they all interfere with free access to the cord, and have no advantages. They were devised on the erroneous supposition that removal of the spinous processes and laminae weakened the spine and interfered with its free movement. The same objections hold good against unilateral laminectomy. The best type of operation is the one most rapidly done and which gives the best possible exposure of the tumour, thus enabling it to be more easily removed with the least danger of any damage to the cord.

In my opinion, the operation of laminectomy as devised and developed by Victor Horsley, and which is still carried out at the National Hospital, Queen Square, represents the simplest and best procedure for the exposure and removal of spinal cord tumours. The anaesthetic is ether given by the intratracheal method. If a general anaesthetic is contraindicated, local anaesthesia, either by Trazier's or by Heidenhain's method, may be used. The position of the patient may be prone, or semiprone, or lateral. I prefer the latter; it interferes less with respiration, opens out the arches of the laminae at the site of the operation, and allows of better drainage of fluid during the operation, thus doing away with the necessity of frequent sponging, which, however, may be obviated by the use of a suction apparatus.

The skin incision is made in the middle line directly over the spinous processes which are to be removed, and carried down at once to their tips, which are exposed. The fascia and muscular attachments are then freed from the spinous processes by cutting against the bone, and reflected on either side. With a broad raspator the muscles and periosteum are cleared cleanly off the laminae on one side, deeper and deeper retraction being used as the procedure is carried out. Any bleeding is stopped by packing gauze into the cavity, and it is rarely necessary to use artery forceps. The same procedure is carried out on the other side. With the muscles well retracted, the spinous processes are removed by cutting through their bases with strong bone-cutting forceps. The laminae are then removed from below upwards by cutting through on either side with bone forceps. A chisel and hammer should never be used, and a saw is quite unnecessary. The epidural fat is now exposed, and when removed the dura is laid bare. Close inspection should now be made to see if the dura pulsates, or whether any extradural tumour is visible or is distorting the shape or position of the dural sac from pressure on its ventral surface. Any manipulations of the dural sac must be of the gentlest. A large size malleable probe may be passed very carefully upwards and downwards, first on the dorsal and then on the ventral surface of the dura, to see if there is any obstruction beyond the limits of the exposed area of dura.

Having decided to open the dura, it is seized and steadied by a pair of fine-toothed forceps and a small opening is made in a vertical direction with a fine knife. The opening is then enlarged to the full extent of the exposed dura, the cut edges of the dura being seized and retracted with fine long artery forceps, or by traction sutures passed with a fine round bodied curved needle. To absorb any slight oozing of blood it is advisable to place small pieces of gauze ("cigarettes" or pieces of dental roll) on each side of the dural sac against the cut edges of the laminae. This keeps the operation field clear and prevents blood escaping into the thecal canal.

If the tumour lies in its most frequent situation—that is, on the postero-lateral aspect of the cord—it is at once visible. If it lies on the ventral aspect of the cord, the latter will be pushed backwards and to one side. Should no tumour be discovered, close inspection should be made as to the presence or absence of cardiac and respiratory pulsations in the cord, the condition of the posterior veins, and as to whether cerebro-spinal fluid continues to escape or not.

The presence of pulsation, the combined escape of cerebro-spinal fluid, and a normal condition of the veins is strong evidence that the exposure is too high, the contrary conditions, that it is too low. Careful exploration on both aspects of the cord with a large knob-ended probe, bent at an appropriate angle, in either an upward or downward direction as indicated, may give evidence of a definite block beyond the exposed area. Elsberg advises also the compression of the jugular veins (Queckenstedt's phenomenon) as being very useful in determining whether one is above or below the tumour level. If a free gush follows the compression it is presumptive evidence that one is above the tumour, and vice versa. In either case the laminectomy is extended in the direction indicated.

After removal of the tumour the dura is closed by an interrupted or continuous suture of fine catgut. The gauze rolls on either side of the dural sac are removed, the muscles are united, layer by layer, with interrupted sutures of strong catgut, and the fascia covering them in like manner. The skin incision is closed with interrupted silk-worm-gut sutures. If an extensive laminectomy has been performed in the cervical region, it is as well to incorporate a well padded long light splint, extending from the mid-dorsal region to beyond the head, in the dressing.

Technique for the Removal of the Tumour

The most important point in the removal of spinal cord tumours is the avoidance of any injury to the spinal cord. Their removal should always be attempted by working away from the cord. If possible, the cord itself should never be handled with fingers or instruments and any sponging necessary must be of the very gentlest. Any nerve roots implicated should be gently disengaged from the tumour, care being taken not to make traction on them away from the cord.

Should one or more posterior roots be incorporated in the tumour they should be divided. It is better to do this than to incise the tumour in an attempt to free the roots. If an anterior root is involved every endeavour should be made to preserve it, but occasionally this is impossible and it has to be divided. One should endeavour always to remove the tumour in one piece with its capsule.

If the tumour is meningeal in origin (the so-called dural endothelioma), and dorsal or dorso-lateral in situation, it will usually be lifted clear of the cord on retraction of the incised dura. It is very seldom adherent to the cord itself, though it may be to the posterior root or a slip of the dentate ligament. The dura is incised around the attachment of the tumour and removed with it. Before doing this it is well first to separate the tumour from any attachments it may have to cord, root, or ligament.

If the tumour lies on the ventral or ventro-lateral aspect of the cord its removal is one of greater difficulty. This may be lessened by a more extensive removal of the bone on the same side as the tumour. To displace the cord lying over the tumour a slip of the dentate ligament is seized in fine forceps and cut from its dural insertion. By traction on this the cord is rotated and drawn to the opposite side. Additional ease of approach, if required,

can be obtained by also cutting one posterior root above and below the severed dentate ligament. It is better to do this than to risk damage to the cord by forcible displacement of it by instruments.

A tumour lying among the roots forming the cauda equina may give rise to great difficulty in its removal owing to several, or even many, of the roots being incorporated in the tumour growth. In may therefore result in only so much tumour being removed as can be accomplished without doing irretrievable damage to a large number of roots, or, as advised by Elsberg, the operation may be done in two stages, the dura being opened and the tumour exposed at the first, and ten days to a fortnight later the wound reopened. It may then be found that the tumour has freed itself from many of the roots previously involved, and can be more safely removed, either in whole or in part.

Removal of Intramedullary Tumours

This is best attempted by the "extrusion" method introduced by Elsberg. Its basic principle is a decompression operation with exposure of the tumour, followed by an interval of time to allow the increased pressure within the cord to extrude the tumour, in whole or in part. Having satisfied oneself that the tumour is intramedullary the swelling is first aspirated with a fine hypodermic needle to exclude the possibility of its being due to fluid. If no fluid is obtained, an incision is made very carefully and slowly by means of a fine von Graefe knife into the cord, just to one side of the postero-median septum to avoid the series of small median arterial branches which enter the posterior fissure. As soon as the tumour is exposed it will begin to extrude itself, but no attempt is made to remove it. A piece of Cargile membrane is placed over the cord and the wound closed, leaving the dura unsutured. A week later the wound is reopened when it will be found that, if the tumour is localized, it will have been almost entirely extruded from the cord, and can be easily removed. If it is an infiltrating growth, the extruded portion can be removed and the remainder left undisturbed. Should no extrusion of the tumour take place, however, it is wiser to be content with the decompression only, rather than risk damaging the cord by attempting to remove the tumour. Good results have followed such a procedure at my hands.

Benign extradural growths, as a rule, offer no great difficulty in their removal, unless they extend all around the dura or lie on its ventral surface. It is a *sine qua non* in these cases that the bone be widely removed on one or both sides, as may be necessary, to obtain easier approach. Several posterior roots may have to be sacrificed in order to allow of displacement of the dural sac sufficiently to gain access to the tumour. In cases of osteoma or chondroma growing backwards from a vertebra or intervertebral disc it is easier to open the dura, rotate and displace the cord as previously described for intradural growths, and then cut through the dura lying over the tumour and remove it through this opening.

The discussion of the treatment of spinal cord tumours would not be complete without the inevitable reference to x rays and radium therapy.

Elsberg has never seen any permanent good results from x rays or radium in irremovable intramedullary growths, but in some irremovable extradural tumours he says that the progress of the disease seemed to be checked for a time. Frazier says that it is incumbent upon the surgeon, in the presence of an inoperable growth to resort to the use of one or other of these agencies the selection to be left to the x ray specialist. Peiper is of opinion that it is a mistake to attempt to replace operation by irradiation in the treatment of spinal tumours.

French authorities are more enthusiastic though cautious. Sicard, Calk, Hagneman and Wallach consider that radiotherapy is efficacious in all types of tumour, but only in a small number of them. As a sequel to operation they advise its use only in gliomata and endotheliomata, four or five weeks subsequently if the symptoms persist but not in benign growths. They attach great importance to the cerebro-spinal fluid below the lesion. If it is normal, in a case in which the paraplegia has become

stationary after post-operative improvement, radiotherapy is useless. They end up with a warning against exaggerating the definite curative value of radiotherapy, and call upon the pathologists to adopt a universal terminology for the different types of tumours, and at the same time to group them according to their radio-sensibility or their radio-resistance.

THE CONTROL OF DIPHTHERIA AND SCARLET FEVER *

BY

R. A. O'BRIEN, C.B.E., M.D.,

Wellcome Physiological Research Laboratories, Beckenham, Kent

DIPHTHERIA

I ANTICIPATE that those who join with me in opening the discussion will agree that with swabbing, testing for virulence to detect the true diphtheria bacillus, Schick-testing, active immunization with prophylactic, and, in emergencies, passive immunization with serum, we can control an outbreak or prevent outbreaks—if the population concerned is disposed to take full advantage of these measures. Just as surely as Pasteur and his hostile critics, when they saw in the dawn on the farm at Pouilly-le-Fort the vaccinated sheep quite well while the unvaccinated lay dying of anthrax, know that complete control of that disease was available to those who wished, so the medical administrators of the large fever hospitals and residential schools know that they can promise the almost complete abolition of diphtheria amongst the nurses or pupils. Applied to the general population the problem passes out of the narrow field of experimental observation on small groups of people with complete controls, and other considerations, economic, social, and political, play a part.

THE PRACTITIONER'S PART IN CONTROL

The control of any infectious disease rests upon the joint work of the general practitioner and the public health authorities. From communications with general practitioners I would with considerable trepidation suggest that perhaps the busy practitioner, faced with the call for quick decision in daily practice, would welcome a short didactic statement by the Association somewhat on the following lines.

Patient—If a patient has the smallest amount of membrane in the throat or nose, or any sudden difficulty in breathing, and any suspicion of diphtheria arises, take a swab if you wish, but give antitoxin at once. The risk to life from the act of giving serum is probably 1 in 60,000, whereas the average risk to life from diphtheria is 3 to 10 per cent, every hour's delay in giving serum increases the risk.

Contacts—The ideal course is to test all contacts by Schick's method and, after separating the Schick-negative reactors—amongst whom will be found any dangerous "carriers" of virulent bacilli—concentrate attention on those giving a positive reaction. See them daily (in order to detect cases of diphtheria at the earliest moment and give serum immediately), or, if that is not possible, consider protecting this group with serum. After the emergency is over, protect them by active immunization. If the Schick test cannot be done the general line of action is the same—that is, inspect daily, or, if necessary, protect with antitoxin.

RESPONSIBILITY FOR DEATHS FROM DIPHTHERIA

In the *Weekly Bulletin* of the City of New York Department of Health for February 5th, 1927, occurs the following statement:

In diphtheria there were 56 such deaths. The parent delayed in calling a doctor from one to five days in 46 cases, usually because "home remedies" were considered sufficient. The doctor delayed the administration of antitoxin for a period of from one to fourteen days in 29 out of the 56 cases. In 14 cases the

doctor's first diagnosis was wrong and in 13 cases he was doubtful. The wrong diagnoses were usually colds and tonsillitis, pneumonia, indigestion, and in one case tetanus.

In 1920 Carey¹ published a valuable analysis of 1,000 deaths from diphtheria in the State of Massachusetts. He points out the difficulty of obtaining positive cultures in the early stages of laryngeal diphtheria and also that the nasal type had been frequently "missed."

With regard to the parents' responsibility, 23 per cent of the children were ill a week, and 4 per cent ill from one to two weeks, before a doctor was called in.

An alarming percentage of 118 of our cases were found moribund upon visitation by the physician. In some instances it was noted that physicians waited for a laboratory report from their cultures before administering antitoxin. In 29 instances it was found that less than 3,000 units of antitoxin were administered. The usual doses, however, seem to have been from 6,000 to 9,000 units. In no instance did we find antitoxin given intravenously. It is most earnestly recommended that this procedure be used in those cases which are seen late in the disease.

I have been unable to find any English official figures of the kind, but probably a medical officer of health with long experience in any large English city could produce somewhat similar records. A confidential "inquest" into every death from diphtheria by a tactful medical officer of health who has the complete confidence of the practitioners in his area would probably yield information of value. The ascertainment of the "parents' responsibility" for late summoning of the doctor would give data of use for public propaganda, and any information relating to delayed medical diagnosis or too small dosage with antitoxin would obviously be of value to the medical men concerned.

GAPS IN OUR KNOWLEDGE

There do not seem to be readily available any large groups of figures indicating how long the Schick-negative condition lasts. Parish and Okell have recently completed a valuable survey which will shortly be published. I am indebted to them for permission to quote some of the figures. In approximately 1,000 children re-tested from one to seven years after giving a negative response, 87 per cent gave a completely negative Schick reaction. Any reaction not clearly negative was read as "positive." About 500 of the children had originally been "naturally" negative to the Schick reaction, of these 89 per cent remained negative, 4 of those read as "positive" were potentially immune, and rapidly developed antitoxin as the result of the Schick re-test, only 2 were definitely positive with no circulating antitoxin and required re-immunization. Amongst about 450 who had been originally immunized until they showed a negative reaction, 85 per cent remained negative, 5 per cent were positive or "faintly positive," and became negative as the result of the first re-test, while again 2 "immunologically obstinate" children, brother and sister, required re-immunization.

Degree of Immunity Represented by a Schick-negative Condition

Another gap concerns the degree of immunity represented by a Schick-negative or "immune" condition.

Immunity is relative and not absolute. From the point of view of immunity against diphtheria the population of an ordinary town cannot be divided into sharply defined groups of "white" (or "immune") and "black" (or "non-immune")—there are a few of varying shades of grey. In large groups immunized long ago there are some what more in the "grey" section.

When the diphtheria bacillus attempts to attack the "white immune" its attack fails, it prevails against the non immune, and clinical diphtheria occurs. In the case of the "grey," whether the attack succeeds or not depends on the weight of the attack and on the amount of white (or grade of immunity) in the grey—that is, whether the attacked has available a store of antitoxin in his blood, and, probably more important, whether his cells are trained and alert so that they can produce speedily and abundantly the needed antitoxin. Fortunately this potential immunity remains even when the circulating antitoxin has, long after a successful course of immunization leading to the production of a Schick-negative condition, fallen to a very small amount—that is, less than one two-thousandth of a unit of antitoxin per cubic centimetre. The indi-

* Read in a discussion in the Section of Preventive Medicine of the Annual Meeting of the British Medical Association, Cardiff, 1928.

vidual in question, as shown by Glenn some years ago for rabbits and guinea-pigs, and recently by Parish and Okell in their observations on children, will respond very rapidly to an assault by toxin. Whether this assault be in the form of a Schick test, or a dose of prophylactic, or the growth of true diphtheria bacilli during an attack of sore throat caused by some other organism, the individual will at once make large quantities of antitoxin, enabling him to throw off the attack with very little disturbance, and with no danger of subsequent paralysis or other sequels.

Possible Improvements in Testing and Immunization

The test is on a reasonably firm basis. We may some day succeed in making a toxin so pure that a control injection of heated toxin will not be necessary, but so far no one has succeeded in doing this. We may also, if we wish, combine the first test and an immunization dose. W. H. Park does this in young children by giving the first dose of his toxin-antitoxin mixture subcutaneously. A week later the reaction in a Schick-positive reactor can be easily read. The mixture commonly used in England—toxoid antitoxin—will not give a Schick reaction because toxoid is used and not toxin in making the mixture. A. T. Glenn has made a mixture, called D P I M, which on intradermal injection into guinea pigs gives excellent results. It indicates the condition of immunity by giving a positive or negative Schick reaction, and it simultaneously immunizes. The mixture has not been widely used in human beings, in adults a considerable amount of "pseudo-reaction" is produced, and the Schick response cannot be read until some days later, there is no reason to doubt that the immunizing effect in children would be as satisfactory as in animals, but observations have not been done on a sufficiently large scale to warrant any statement. We are not quite convinced that this is the most promising line to pursue, and have for the moment given up this work.

With regard to prophylactic injections, the three materials which at present hold the field are toxin-antitoxin (U. S. A., 0.1 L+), toxoid-antitoxin (Britain), and toxoid ("anatoxine," France, etc.). The possibility of undesirable sensitization by the minute amount of antitoxin present in the first-named two mixtures has attracted some attention during the past two years. Gordon² writes:

'As the result of a recent active campaign in Detroit for toxin-antitoxin prophylaxis against diphtheria it became evident that a considerable proportion of the patients admitted were hypersensitive to horse serum.'

Dr. Stewart of Minneapolis³ describes serum reactions in seven children who had been previously immunized. Dr. Stewart courteously informed me that these seven were the only children previously immunized against diphtheria into whom he had subsequently injected serum, and all seven had reacted. (See also Lathrop⁴ and Gatewood and Baldrige⁵ in favour of sensitization, and Park⁶ and Backer,⁷ experience refuting serious sensitization.)

It would appear from the experiences of the eastern States of the United States of America and England that immunization with the New York or the English mixtures containing antitoxin rarely if ever produces a condition of "sensitization" sufficient to give rise to serious serum sickness following the injection of serum at a later date. Dr. Sophie Spicer⁸ has recently published a series of observations. Her group of 28 children given scarlet fever or other antitoxin some time after a toxin-antitoxin injection showed a 14.3 per centage of serum reactions. This reveals no sensitization through prophylactic injections, for of 164 control children who had not been immunized, 13.4 per cent gave reactions.

In England inquiries have so far revealed no instance of "sensitization" in this sense. The experience of Gordon and Stewart therefore appears to be exceptional. However, it is possible to-day to make a prophylactic "toxoid" of high value containing no antitoxin, and this toxoid is available in almost all countries. During the past year or two the immunizing properties of the floccules produced in the Ramon test have been much worked with, since the discovery by Hartley in 1923 that they were antigenic. It was hoped that, being more or less insoluble, the floccules might keep up a continuous stimulus and that in this way one injection might be sufficient for immuniza-

tion. It is doubtful, however, if one injection will be sufficient, and further experience must show whether this antigen has any real advantages over the ordinary ones. Glenn and Pope⁹ found that toxoid antitoxin floccules also have high immunizing value.

Glenn and Waddington emphasize the importance, in estimating the value of prophylactic, of dose and interval. These two authors kindly permit me to quote the following conclusions from some work yet unpublished:

I. Guinea pigs (approximately one hundredth the weight of a child) can be immunized by a single injection of 1 c. cm. of toxoid or toxoid antitoxin mixture.

II. The fact that a single dose of 1 c. cm. of prophylactic fails to immunize human beings suggests that dose depends to some extent on weight.

III. Because two or more doses must be given, the value of the prophylactic must depend on the power of the initial injection to produce potential immunity.

IV. Antigens should be judged by the immunity produced in guinea pigs after two injections of 0.01 c. cm. (one hundredth of the human dose) given at an interval of three to four weeks (the interval that should be observed in human immunization).

V. With this minute dose of T A F (toxoid antitoxin floccules) and this interval, 21 of 25 guinea pigs became negative to the Schick test ten days after the second injection, whereas with toxoid or toxoid antitoxin mixture only 5 of 21 became negative. A comparison of these three antigens by the ordinary methods of test, which rest upon judging the value of antigen by the immunity produced by one large injection into guinea pigs, fails to bring out this important difference.

The suspension, in addition, seems to be free from liability to cause local reaction in human beings. In a recent series Okell and Parish found that 45 of 56 subjects became Schick negative when tested from one to five months after one, two, or three doses of T A F. This promising work is being continued.

Carriers.—Much interesting work has been done in connection with the detection of virulent diphtheria bacilli in the throat and nose of the convalescent before discharge, and of the "carrier," and the limited value of this swabbing has been emphasized because the "intermittent carrier" may only at times yield diphtheria bacilli in the subculture. This is true, but in the course of examination of large numbers of subcultures we have occasionally been impressed by finding a smear from a carrier which is practically a pure culture of Klebs-Loeffler bacilli, and under the microscope resembles in every respect a culture smear from a diphtheritic throat. We have been in the habit of calling such people "profuse" carriers, as opposed to the "sparse" carrier who may yield only one or two colonies of Klebs-Loeffler bacilli in a large blood plate, and we cannot avoid the conviction that such "profuse" carriers are as dangerous to those in the neighbourhood as an acute early case of diphtheria. McCartney¹⁰ points out that a "sparse" carrier to-day may be "profuse" to-morrow.

SCARLET FEVER

So far as scarlet fever is concerned the story is much the same as for diphtheria, save that we must here be less dogmatic, our ground is not so firm.

The patient admitted with frank clinical diphtheria who has not received serum is practically invariably a "Schick-positive reactor", the Dick test is usually, but not always positive in the patient admitted during the early stage of scarlet fever. (The variations in the statistics dealing with this point in different parts of the world will probably lessen or disappear when there has been international agreement on the strength of Dick toxin to be used for testing.) Whether the suggestion arising out of the very interesting work in America by Dochez¹¹ and colleagues, that the Dick test is a purely allergic response to the protein or other constituent of the streptococcus and is not a response to true toxin as in the Schick test is true or not we do not at present know. As opposed to this hypothesis it appears to be reasonably certain that if only nurses who react negatively to the Dick test are allowed to take duty in scarlet fever wards it will be found that these nurses do not catch scarlet fever. Further we can consistently convert the reaction of 'Dick positive' children who have been in contact with scarlet fever to negative in twenty-four to forty-eight hours by giving 5 c. cm. of concentrated scarlet fever antitoxin. These children remain negative for

some days, and do not develop scarlet fever. The hypothesis that the reaction is a pseudo reaction to toxin similar to the Schick response is in accordance with these observations, and is the simpler one to hold for the moment while further research is proceeding.

It is a matter for regret that the important questions of optimum dosage of prophylactic, and interval between injections, have not been more widely investigated in England. When more detailed knowledge is available it will be easier to progress rapidly with "double" or simultaneous immunization against diphtheria and scarlet fever.

Schultz-Charlton Test—This test is being used in diagnosis. Its value and its limitations are being more clearly ascertained.

ACTIVE IMMUNIZATION

The average patient suffering from moderate uncomplicated scarlet fever will lose his rash and be on the way to recovery by about the fifth to the seventh day. At this time the Dick-positive percentage among patients begins to drop. The immunological phenomena seem clear—the patient will lose his rash promptly if given sufficient antitoxin to make him negative to the Dick test, if untreated with serum he cures himself by the development of antitoxin, at first hidden in his cells, then rapidly produced in abundance and easily detectable in the blood. It is probable that if we could choose a dose of toxin which, when given to the average Dick-positive reactor, would produce an amount of constitutional disturbance, rash, vomiting, temperature, etc., for five days, comparable to that produced by an average attack of scarlet fever we would achieve a similarly rapid immunity. Inasmuch as the dose of toxin is a self-limited one—and not as in true scarlet fever a possibly unlimited quantity produced by the growing streptococci in the throat—the patient would be almost certainly safe from any real harm. One could thus probably immunize against scarlet fever in seven to fourteen days a patient willing to put up with the inconvenience outlined above. It is known as the result of early experiments, some unintentional, some not, that a dose of toxin sufficient to cause "scarlatinoid syndrome" produces rapid immunity. This is, of course, impracticable as a general means of immunization.

In immunization with toxin the tendency is towards large dosage. Dr. W. H. Park kindly informed me recently that he is giving 30,000 to 40,000 doses in five injections. Among 10,000 children in institutions there have been no instances of scarlet fever attacking those immunized. Of the children strongly positive to the Dick test before immunization about 20 per cent changed to positive within two years. I am indebted to the courtesy of Dr. G. L. Kiefer, Commissioner, Department of Health, Michigan, for the information that the present practice in that State is to give three injections, two weeks apart, of 500, 3,500, and 30,000 skin doses. This course is yielding a high immunization rate. On the other hand, it is of interest that Kinloch, Smith, and Taylor,¹² with much smaller dosage—that is, weekly injections of 500, 1,000, and 3,000 skin doses—record a Dick-negative percentage of 75 four months later.

Some work has been done with toxin treated with formalin and sodium ricinoleate. Immunologists do not seem to have been very successful in producing a satisfactory formalinized toxoid. We have ourselves tried, without success. Professor Perkins¹³ records the treatment of 8,000 children with ricinoleated toxoid. When only one dose had been given the incidence per 1,000 was two and a half times greater in the untreated, and when two doses had been given it was more than six and a half times. It is possible that equally favourable results have not been obtained elsewhere, or that controlled experiments have not been made in the United States of America on a sufficiently large scale, for this immunization with ricinoleate toxoid has not yet come into general use. Korschun and Spirina¹⁴ in Moscow record considerable success with moderate dosage both of toxin alone and of toxin plus vaccine.

SERUM TREATMENT

The dosage of antitoxin in ordinary attacks of scarlet fever has become more or less standardized, and ranges from 10 c.c.m. intramuscularly in the mild case to 50 or

more c.c.m. in the severe attack, the antitoxin being given intravenously, at least in grave cases. Dosage waits to some extent on more accurate methods of titration. Of the methods of titration in which human volunteers are necessary the determination of the minimum efficient prophylactic dose (that is, from 2.5 to 5 c.c.m. of a good concentrated serum) is probably the most accurate, the Dick skin neutralization method next, and the Schultz-Charlton dilution method last. The Parish-Okell rabbit method is probably at least as accurate as any of the others, and has the great advantage that it does not require human volunteers. Serum is efficient in cutting short temperature, malaise, and rash, and shortening convalescence, and when given early apparently reduces the chance of the occurrence of complications, but if septic complications, such as otitis, mastoiditis, or septic adenitis, do make their appearance, no serum yet produced seems to promise a certain cure or amelioration. Cases are from time to time reported in which the injection of serum during this septic stage has been followed by rapid improvement, many clinicians will probably, therefore, feel it their duty to try serum even in septic cases until a more efficient means of treatment is discovered.

CONVALESCENTS

With regard to the formidable question of the discharge of convalescents after scarlet fever without danger to the fellow members of the family and to schoolmates, little progress has been made. It is certain that many convalescents are discharged with haemolytic streptococci present in the throat indistinguishable from true scarlet fever streptococci by any test we possess. Since the streptococci may persist for many months in a considerable number of children, a rigid policy of incarceration of these children until the throat is clear is impracticable. The medical officer of health at present faced with this difficult situation can merely adhere to the safe rule that as soon as a convalescent is restored to completely normal health with no discharge from any mucous membrane, etc., he can be released, but as long as he has any discharge he should not be released without grave consideration of demand for "negative cultures" before release would at present probably quickly clog administrative measures.

An interesting method of trying to abolish "return" cases has been tried by American workers and by Kinloch and colleagues (loc cit.). All contacts are Dick-tested and the positive reactors given three or four doses of toxin—for example, 500, 1,000, 3,000 skin doses at five-day intervals. The latter authors reported that by this method they were able to make a reasonable percentage of contacts negative before the patient returned from hospital.

SUMMARY AND CONCLUSIONS

Diphtheria

- 1 Modern methods of detection and prophylaxis, where the population concerned will allow the medical officer full scope, give practically complete control of diphtheria.
- 2 Attempts to make and introduce improved prophylactics—for example, toxoid and floccides—are described.
- 3 The rare instances of "diphtheritic tonsillitis" or "modified diphtheria" in people who have been negative to the Schick test are discussed.
- 4 The "profuse" carrier probably spreads as much diphtheria as an early case of the disease.

Scarlet Fever

- 1 Further knowledge has been gained of the value and limitations of the Dick test, Schultz-Charlton test, passive immunization of contacts, active immunization, and of treatment with antitoxic serum.
- 2 Further work is necessary to determine the optimum method of immunization against scarlet fever alone, and also by "double" or simultaneous inoculation against diphtheria and scarlet fever.

OCCUPATIONAL CANCER OF MULE-SPINNERS^{*}

BY

A. H. SOUTHAM, M.D., M.Ch. Oxon., F.R.C.S.,
HONORARY ASSISTANT SURGEON, SALFORD ROYAL HOSPITAL ASSISTANT
SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY, LECTURER IN
OPERATIVE SURGERY, MANCHESTER UNIVERSITY

The peculiar liability to skin cancer of workmen in certain trades, as a result of their occupation, has been recognized for over a hundred years. It was only in 1922, however, that we first drew attention¹ to the occurrence of epithelioma of the scrotum amongst mule-spinners in South Lancashire as the result of the soiling of the clothes in the region of the scrotum by the lubricating oil used in the cotton spinning machinery.

The experience gained since that time and the clinical observations made of a large number of cases have enabled certain definite conclusions to be drawn as to the earliest signs, clinical features, and treatment of this type of skin cancer.

INCIDENCE OF MULE-SPINNERS' CANCER

Epitheliomatous ulceration occurring in mule-spinners is usually found in operatives over the age of 50 years, though cases may be met with in younger men. It is only seen in those who have worked in the mill for long periods—rarely less than ten years.

The most common situation for the lesion is on the left side of the scrotum, but about 25 per cent occur on other sites—namely, the forearm, face, and neck. The skin of the leg appears to be remarkably resistant to the action of mineral oil and is an infrequent site for spinners' cancer.

Over fifty cases of scrotal cancer occur in spinners each year, and the incidence of the disease is very much higher among persons employed in mule spinning than in any other class of worker. Approximately 2.5 per 1,000 mule-spinners develop this disease. It is probable that idiosyncrasy plays a part in the development of these epitheliomata, and that a dry skin is an important etiological factor in carcinoma of the skin.

CLINICAL FEATURES

The first clinical evidence of an epithelioma is a localized hyperplasia of the keratin producing a layer of the skin, clinically suggesting a warty plaque. This is followed by a secondary round-celled infiltration of the underlying corium, the demarcation of the epithelial layer from the subcutaneous tissue remaining sharp. Within a widely varying period of time epithelial cells appear to break through the dividing line and a true prickle-cell carcinoma develops. At this stage the lesion is about the size of a pea, is freely movable, and is relatively benign, though it must always be regarded as potentially malignant. It is covered with scales which the man may remove by scratching, leaving a small bleeding surface over which a scab forms. Such lesions may be present for months or years in a benign form before they show any of the characteristics of malignancy. In some cases the condition appears on a chronically inflamed skin secondary, no doubt, to the prolonged contact with oil, and this condition is apparent before any wart formation.

Although frequently single, these lesions may be multiple, developing over a period of years. Sooner or later localized sloughing occurs and signs of inflammation around the lesion, due to secondary infection, follow. Definite ulceration ensues and the growth may then appear as a tumour, the size of a small cherry, raised above the skin, with a moist and red-coloured base. The growth extends peripherally and has now all the characteristics of malignancy and bleeds easily when touched. At this stage the disease is entirely local and the lymphatic glands are not yet involved, though they may be enlarged as the result of inflammatory infection. Malignant invasion of the glands is, however, bound to occur sooner or later, the length of time varying according to the situation of the growth and the extent of the underlying round-celled infiltration.

The glands are affected much earlier when the lesion is situated on the scrotum than when the primary lesion is situated elsewhere, these latter tumours being of relatively

low malignancy. As the disease progresses the glands tend to break down, and death ultimately occurs from septic absorption, exhaustion, or haemorrhage from the underlying vessels. Metastases in distant organs are only seldom found.

The occurrence of cancer of the skin amongst female cotton operatives is uncommon, but a case of epithelioma of the forearm has recently been observed in a female cardroom worker. This case was of interest in that the patient showed, in addition, a marked atrophy and dryness of the skin of both hands, forearms, and arms up to the level protected by clothing, and a similar condition of less severe degree occurred on the exposed areas of the face and neck.

TREATMENT

Mule-spinners' cancer is a most favourable type of malignant growth for surgical treatment as it can be detected at a very early stage and complete removal is then a comparatively simple matter. The most malignant type of growth is that which occurs on the scrotum, and when in this situation it is very liable to be followed by secondary deposits in the lymphatic glands, and therefore requires a more radical operation for its complete removal. It is essential that all warts and papillomata seen on the skin in mule-spinners should be regarded as potentially malignant, for when malignant degeneration supervenes it always arises in one of these warty hypertrophies.

I am strongly of the opinion that excision of these growths is the only treatment to be considered, as, in my experience, treatment by radium or x rays does not appear to give such satisfactory results. In the early stages, before ulceration has occurred, the growth is relatively benign, and local removal is sufficient to eradicate the disease, as malignant invasion of the glands has not usually taken place.

When a definite ulcer is present an extensive operation, involving removal of the growth with an area of surrounding skin and excision of the lymph-bearing areas, must be carried out. This is especially important in scrotal cases and removal of all the glands in both groins must be practised, since, although the growth may be found on the left side, the glands in both groins are often invaded owing to the free anastomosis of the superficial lymphatics across the mid line of the scrotum.

The excision of the lymphatic nodes in the inguinal regions must be complete, and the operation must include all the fat and glands in this region and the upper part of the saphenous vein. No lymph channels appear to pass the inguinal glands to reach the iliac glands direct, and primary infection is found only in the former. Prophylactic application of x rays may be given for twelve months after operation.

PROGNOSIS

The prognosis in this disease, as already stated, is good, as in other types of skin epitheliomata, when the lesion is detected in the early stages. Cases of scrotal cancer have been under observation for varying periods up to ten years that have remained free from recurrence after operation. But when the glands are invaded the outlook is serious and recurrence is very liable to take place. In 13 cases of scrotal cancer with involvement of the lymphatic glands, treated during a period of two years, recurrence or death followed in 9 cases (70 per cent), and only 4 patients (30 per cent) remained alive and well at the end of this period. Prophylactic applications of x rays had been given to these patients, but appeared of little value in preventing glandular or local recurrence of the disease.

This tendency to local recrudescence is well illustrated by the case of a man aged 32, who had worked as a mule spinner for twelve years. In 1925 he underwent a radical operation for epithelioma of the scrotum and removal of the glands in both groins. Since then I have removed four further epitheliomata from the scrotum (all confirmed by microscopic examination)—in October, 1926, June, 1927, December, 1927 and July, 1928.

Such cases as this are not uncommon in my experience, and emphasize the importance of frequent medical examination particularly amongst operatives who show a tendency towards this condition.

* Read before the International Cancer Conference held in London on July 18th 1928.

The disease, when it occurs on other sites of the body, is much less serious, and involvement of the lymphatic glands is a considerably later phenomenon, but in these cases also, when neglected, death from ulceration, secondary infection, and hæmorrhage follows as in scrotal cases.

MULTIPLE PRIMARY MALIGNANT NEW GROWTHS

An interesting feature occasionally met with is the development of a carcinoma of the skin and a second malignant new growth elsewhere in the body. This phenomenon has received little attention from pathologists, and is of importance from a medico-legal aspect when the second new growth is the actual cause of death.

Cases of epithelioma of the scrotum have been found associated with carcinoma of the stomach, tonsil, and lung, and in these cases an epithelioma of the scrotum had been removed by operation, the second new growth developing subsequently.

A record of such phenomena is of considerable interest, for while it has been assumed that the development of one malignant new growth tends to inhibit the subsequent development of a second, owing to some increased resistance in the individual, it is possible that the conditions may be somewhat different in the case of skin cancer.

CONCLUSION

In conclusion I would emphasize the importance of the diagnosis of mule-spinners' cancer at an early stage, when operative treatment is a simple procedure and is followed by lasting cure.

By educating the workers to pay prompt regard to any warts or small sores on the skin, and the profession to realize the importance of early diagnosis and treatment, the proportion of cures will steadily increase and the number of radical operations progressively diminish.

At the present time there is no safer method of cure than by surgery, and we can secure most satisfactory results. No doubt the time is not far distant when other and better remedies may be discovered or effective preventive methods be adopted, by means of which mule-spinners' cancer as an occupational disease will be totally abolished.

TELESCOPIC SPECTACLES *

BY

A. H. LEVY, M.D., C.M., F.R.C.S.,
Surgeon Central London Ophthalmic Hospital

TELESCOPIC spectacles are low-power wide-angled Galilean binocular telescopes made as compact and as light in weight as possible, so that they may be used constantly as spectacles in the ordinary way without serious disfigurement or discomfort.

Correcting telescopic spectacles were first proposed for highly myopic patients towards the end of the eighteenth century. H. Dixon in 1785 patented a method of making such spectacles (Patent No. 1375, December 14th, 1785). He first started with two spherical mirrors, but later replaced these by spherical lenses. As a matter of curiosity it may be mentioned that Eschmair in 1660 described a similar system suitable for close work. After Dixon many workers occupied themselves with the problem, notably W. Kitchiner, in a book published in London in 1824, but owing to various causes the results were not very good and the method was not much used.

In recent times the problem was raised afresh by Professor Hertel of Strasburg. He was led to consider this problem by the publication of Fukala's papers in 1890 and 1895. In these communications Fukala sought to revive the operation originally suggested by Boerhaave in 1708 and Desmonceaux in 1778 of removing the crystalline lens for the cure of high myopia. This operation was

extensively practised, but the very definite dangers impressed themselves upon Hertel, and he sought to find some optical method of improving the acuity of these patients. The details of the problem, as set out by Hertel, were worked out more or less satisfactorily by Dr. M. von Rohr in the research laboratory of Messrs. Carl Zeiss in Jena (see *Archiv für Ophthalmologie*, 1910, vol. 75, p. 561).

The difficulties of designing telescopic spectacles are many, but I will mention only two: first, the astigmatic deformation of obliquely incident light, and secondly, the chromatic aberration.

The astigmatic deformation can be partly overcome by adopting a series of measures: the most important of which are (1) suitably bending the optical elements in the telescope, (2) by limiting the field of vision so that only tolerable distortions of the images are evident at the edges of the field, and (3) by varying the separation of the two elements. This last factor—separation of the two elements—is only of limited use, since the distance between the elements must be exactly the difference of their focal lengths. The chromatic aberration was a great difficulty because it was impossible to make the object glass achromatic on account of the weight, and it was only simplified when Gullstrand showed that the chromatic correction would be sufficient if the chromatic difference of magnification of the principal rays entering the eye was removed—that is to say, the chromatism would be sufficiently corrected for practical purposes in such a low-power telescope by making the eye lens of a combination of a flat and crown glass.

These telescopic spectacles can be designed to give a magnifying power up to nearly two diameters. The usual magnification selected for emmetropic spectacles is $\times 1.8$, and the resulting improvement of vision is due to the image formed on the retina being nearly twice as large as the image formed with the unaided eye or with ordinary spectacles.

In Fig. 1a is given a diagram showing the general optical construction of the spectacles, and the path of the light for a distant object and relaxed accommodation of an emmetropic patient. The relative position of the patient's

FIG. 1a

FIG. 1b

FIG. 1c

eye is shown in broken lines. Fig. 1b shows how the light from the spectacle is refracted by the cornea and crystalline lens of the eye. In Fig. 1c is given a diagram for objects at a finite distance. It will be noticed that only simple lenses are shown for the eye lens, although it is stated earlier in these notes that Gullstrand recommended a cemented eye lens to get rid of chromatic difference of magnification. In recent years it has become possible to secure at a reasonable price optical glasses of such properties that the chromatic trouble referred to can be very substantially reduced by suitable choices of glass of different dispersive powers for the two simple lenses, thus avoiding the additional weight of achromatic lenses. It is improbable that the acuity of vision of patients needing these spectacles would be good enough to appreciate the more precise achromatization which can be obtained by using an achromatic eye lens.

* Read in the Section of Ophthalmology of the Annual Meeting of the British Medical Association, Cardiff 1928.

TELESCOPIC SPECTACLES FOR AMYOTROPIA

Telescopic spectacles are most frequently needed by highly myopic patients. These also are usually made up of two simple lenses of suitable shape and separation, after the style of a Galilean telescope, the rays, instead of emerging parallel from the eye lens, as for an emmetropic spectacle, are made to emerge with the degree of divergence corresponding to the myopia of the patient (see Fig 1d).

FIG 1d

Spectacles are often made up for three or four degrees of myopia—for example, -10 D, -20 D, -30 D—and suitable positive lenses are then added to the eye lens of the nearest excessively myopic spectacle to suit the patient's need. As will be explained later in the text, in connexion with reading spectacles, the addition of a *plus* lens to the negative eye lens tends to assist rather than detract from the good performance of the spectacles.

TELESCOPIC SPECTACLES FOR READING

One pair of telescopic spectacles cannot be used for both distance and reading, even when the wearer is emmetropic and in possession of a fully active accommodation. This is (1) because the accommodative power of the eye is inadequate to overcome the increased convergence produced by the telescopic spectacles (2) because varying the separation would upset the good definition of the image (3) because of the necessity of accurately angling the frames to suit the working distance. In the ordinary way, with simple spectacles or none at all, the accommodation exerted is just the dioptric power of the working distance—for example, $+4$ D for 10 inches and the angling of the frames is comparatively unimportant. In Fig 2a it will be seen that the angle of convergence of light received by the spectacles is increased roughly in proportion to the magnification they give, consequently an eye using $\times 1.8$ telescopic spectacles and a working distance of 10 inches would have to accommodate $4 \text{ D} \times 1.8 = 7.2 \text{ D}$, or to the extent required with ordinary spectacles for an object at only $5\frac{1}{2}$ inches from the eye. Actually owing to the rapid contraction of the beam between objective and eye lens the accommodation demanded by the telescopic spectacles is

FIG 2a

FIG 2b

FIG 2c

even greater than already stated, Theodore Hamblin, Ltd, report that $+10$ D is necessary with their design of spectacles for a 10-inch working distance.

It is usual and more restful to the eyes if the spectacles are used as magnifying loupes and binoculars, with relaxed accommodation for all working distances; in which case it is necessary to add a lens of such power as will make the emergent rays parallel and thus replace the accommodation otherwise required.

There are two methods of obtaining this additional power. First, there is the possibility of adding this auxiliary lens for reading to the object glass, as is shown in Fig 2b (Messrs Zeiss followed this plan). In this case only the exact dioptric power of the working distance is required—for example, $+4$ D for 10 inches, this holds good whatever may be the magnification and construction of the telescopic spectacles. From the designing point of view, of

course, this method is much the simpler and more straightforward, but there are several real advantages, from the patient's point of view, in adding the necessary power to the negative eye lens (see Fig 2c). Theodore Hamblin Ltd, employed this method for the following reasons: in the first place, an additional lens in front of the object glass is very conspicuous and likely to be considerably heavier than the one of smaller diameter behind the eye lens, secondly, for lightness the spectacles are frequently composed of simple lenses, and a positive lens of suitable glass added to the negative eye lens tends to improve the general definition.

OPTICAL FACTS OF IMPORTANCE

From Fig 1a it will be seen that all bundles of rays cross at the point C (the "exit pupil") along the axis. This is the ideal position for the centre of rotation of the eye. Evidently the closer this point C is to the negative eye lens the larger will be the visible field. Figs 3a and 3b show the extreme oblique rays for two positions of the exit pupil C.

FIG 3a

FIG 3b

From the diagrams it will be seen that a ray at a steep angle, corresponding to a larger field, can pass through the lenses when the exit pupil is closer to the eye lens. The position of C affects the quality of image, in particular the flatness of the field, for every design of telescopic spectacles there is a best region for C.

Further, this circular base C, common to all bundles of rays, should be symmetrical about the axis of the system. That is to say, the centre of C should be coincident with the axis. Fig 4a illustrates the effect of a lateral displacement of C (this effect is obtained when the P.D. of the spectacles does not agree with actual P.D. of the wearer). From the diagram of Fig 4a it will be seen that an eccentric exit pupil destroys the symmetry of rays about the optical axis. Additional rays are admitted above the

FIG 4a

FIG 4b

axis, rays normally entering below the axis are excluded (see Fig 4a red rays). In effect the aperture is increased above the axis and decreased below. In practice this eccentricity spoils the symmetry of the visible field and the good definition of the image, and the wearer may be conscious of a vague sense of discomfort in using such spectacles, but unless optically trained will not be able to appreciate the reasons for the discomfort.

More serious and disturbing trouble arises when the telescopic spectacles are tilted before the wearer's eyes—that is to say when the axis of the spectacles is inclined to the axis of the eye (see Fig 4b), and consequently when the common base C of all bundles of rays entering the eye is not normal to the axis of the spectacles. From Fig 4b it will be clear that when looking as one imagines, straight ahead through the spectacles it is actually an outer part of the field that is being used, and the apparent

centric of the field will consequently suffer from the defects unavoidably present at the extreme edges of a large field in a simply constructed optical system. At the edges of the field, corresponding with the periphery of the retina, these effects are hardly noticeable, but in the centre of the field the eye is very critical and at once detects any distortion of the image. The wearer in these circumstances will most certainly complain that all the black lines in anything he is examining through the spectacles have coloured edges, blue on one side or red on the other. If he complains of seeing yellow on the left of his black lines, for example, it is necessary merely to tilt the telescopic spectacle to the left in order to bring the axis of the eye and spectacle into coincidence, or at least to render them parallel. Other effects of this tilting of the spectacles before the eyes will be a source of discomfort to the wearer, the chief of which will be caused by astigmatism of very appreciable amounts.

Another source of trouble may arise in the addition of auxiliary lenses for reading or ametropia. These auxiliary lenses may be of high power, the separation between the auxiliary lens and the eye lens or objective is a matter of real importance, since variation of the separation causes rapid variation of the power of the combination.

PRECAUTIONS NECESSARY IN PRESCRIBING AND FITTING TELESCOPIC SPECTACLES

From the foregoing discussion it will be realized that the accurate prescribing and fitting of telescopic spectacles is of the greatest importance if they are to be of benefit to the wearers. Seemingly small errors in frame measurements in particular may entirely spoil the possibilities of the spectacles, so much so that they may be judged worse than useless, whereas accurately prescribed and fitted spectacles may prove very useful to the same wearers.

To make the testing simple and straightforward it is really necessary to have a special outfit—trial frame, adaptors, and auxiliary lenses—for reading and ametropia, these parts should exactly correspond in essential design with the spectacles subsequently supplied. Spectacles made by different firms for example, even though considered equally good and nominally the same, will be quite sufficiently different in magnification and other details of design to render it absolutely essential to use the trial outfit supplied by the firm which is ultimately to supply the spectacles.

The following points are of importance in testing:

1 The spectacles should be worn as close to the eyes as lashes, etc., will comfortably allow.

2 Great care should be taken in making all frame measurements to ensure that the spectacles will be

FIG 5

accurately centred in every way over the eyes. This is a very much more important matter when testing for telescopic spectacles than for ordinary spectacles. It rests with the dispensing opticians, of course, to make rigid frames which will bear out and maintain the surgeon's careful prescriptions, but spectacle frames of ordinary design are not suitable, as they have proved to be not sufficiently rigid. Fig 5 shows a spectacle frame specially designed for the purpose. It will be seen how rigid the front of the frame is.

3 It is often a matter of difficulty to determine the working distances with any combination of lenses. It is a fact of universal experience that all, except those with long optical practice, tend to exercise their utmost powers of accommodation when looking through instruments. The only way to induce relaxation of the accommodation when

trying out working distances is to bring the test object up towards the patient from a distance, and take the first point at which he sees a focused image as the true working distance. Even this should be tried several times, as the very effort of consciously looking carefully and perhaps nervously seems to induce accommodation which refuses to relax.

4 The auxiliary lenses added in testing should be used in an exactly similar way to those finally supplied. They should be used with the same surface (plane or convex) towards the eye lens, and should be made of glass of the same refractive index as the lenses in the spectacles which will be supplied.

FINAL FITTING OF THE PRESCRIBED SPECTACLES

If the spectacles and frames have been correctly prescribed and made, the wearer should see one image of a black-and-white object at the intended working distance on the optical axis, well defined and colourless. (A black cross two or three inches long drawn on a white card makes an excellent test object.) If there are errors in the framing of the spectacles the patient may complain of seeing two crosses relatively disposed in some way, and/or of seeing coloured edges at the boundaries of the crossed lines. Suitable bending or readjustment of the frames will remedy these troubles. Each eye must be tried separately for the coloured edges. If the yellow edge is to the right, the spectacles need bending to the right, and vice versa similarly, if the yellow edge appears at the top of the horizontal line a bend upwards is needed. If there is not yet binocular vision, and the P.D. is checked and found to be correct, a little further adjustment is necessary in the angling of the frames. The direction of the adjustment required is always opposite to the direction of the displacement of the image—that is to say, if the image is displaced up and to the right, an adjustment down and to the left is required.

THE LARGE STOMA GASTRO-JEJUNOSTOMY*

BY

KENNETH BLACK, F.R.C.S. Eng.,

PROFESSOR OF SURGERY, KING EDWARD VII COLLEGE OF MEDICINE,
AND SURGEON, GENERAL HOSPITAL, SINGAPORE

We seldom read the medical journals of to-day without noting the frequency of papers on the surgery of gastric and duodenal ulcers. While it seems that opinions preponderate that gastro-jejunostomy is an operation giving success in the majority of cases of duodenal ulcer it would appear that it is by no means so effective for chronic non-malignant gastric ulcer, in fact in gastric ulcer in which there is no pyloric obstruction, gastro-jejunostomy, as practised to-day, often gives such unsatisfactory results that more elaborate and serious operations, such as sleeve resection and gastrectomy are advocated and undertaken, with, it is claimed, superior results.

Recently J. Abadie¹ describing the results of 300 operations for gastric ulcer concludes that excision of the ulcer alone does not cure the patient, that gastro-jejunostomy gives a good percentage of cures, but that duodenal-gastrectomy is the most certain of all methods of cure. These conclusions coincide closely with those of many other authorities who have specialized in gastric surgery. Some highly skilled surgeons find that the operation of gastrectomy gives a mortality no higher than that of the more simple gastro-jejunostomy, but such favourable experiences cannot be taken as a guide for the majority of us. On the other hand, Mr R. P. Rowlands² states that gastrectomy has a mortality seven times that of the more simple gastro-jejunostomy—a grave objection to this radical operation. An additional argument commonly advanced in favour of the major procedures is that many of these ulcers, which at operation appear simple, are in fact actually cancerous particularly is this so when the ulcer is of large size, but from the published results of

* A paper read at a meeting of the Malayan Branch of the British Medical Association, September 26th 1927.

gastro-jejunostomy alone for "simple" gastric ulcer the rarity of the subsequent development of cancer goes far to disprove this contention. Of course, the presence of definite malignant ulceration would fully justify the most radical operation.

It will be agreed, I think, that in the treatment of all inflammatory lesions there are two main principles—namely, to treat and remove the cause of the disease, and to rest the diseased part.

In the first place, to treat and remove the cause of gastric ulcer is impossible, as it is unknown at the present time. There appears to be evidence that sometimes the cause of peptic and duodenal ulcers may be secondary to dental sepsis, and in this connexion the following figures, compiled by my house-surgeon, Dr. A. M. D'Cotta, are of interest.

Total Admissions into the General Hospital, Singapore, for the six months ending June 30th 1927, showing proportion of cases of Gastric and Duodenal Ulcers

	Total Admissions	Cases of Gastric and Duodenal Ulcers
White races	818	8 = 1.0 per cent
Chinese	2,490	12 = 0.48 "
Indians	2,007	5 = 0.25 "
Malays	216	0 = 0.0 "
Other Eastern races	90	0 = 0.0 "
Total	5,621	25 = 0.44 per cent

It would appear from this table that among the Malays gastric and duodenal ulcers are rare, and we know that they seldom suffer from dental sepsis. With the Indians dental sepsis is not very common, and among them ulcers are rather infrequent. On the other hand, the Chinese suffer largely from dental sepsis, and in them ulcers are twice as common as among the Indians. In the white races, which include British, Americans, Australians, and Eurasians, dental sepsis is almost the rule, and among them ulcers are four times as common as in the Indians and twice as common as in the Chinese. Further, in dogs both dental caries and peptic and duodenal ulcers are almost unknown.

Secondly, to place at rest completely a gastric or duodenal ulcer is nearly as impossible as to give rest to a diseased heart or lung, but it seems probable that much can be effected by partial relaxation of work. Gastro-jejunostomy alone seems to be successful in the treatment of the majority of duodenal ulcers, the percentage of cures ranging from 85 to 95 according to various statistics. This suggests that the partial rest to the duodenum by short-circuiting the stomach and jejunum suffices to bring about a cure in most of these cases. Why, then, cannot similar satisfactory results be obtained in gastric ulcers? May it be that a stoma sufficiently large to cure the majority of duodenal ulcers is not large enough for equal success in gastric ulcers? I am disposed to believe that this is the case. In the treatment of chronic ulcer of the leg rest in bed and cleanliness will bring about a cure in most cases, and I venture to think that no one would advocate amputation of a leg for simple ulceration, except as a last resort, yet when a simple ulcer occurs in the stomach gastrectomy is recommended by an increasing number of advocates. Furthermore, even after gastrectomy recurrence of ulceration is not by any means unknown.

It would be comparatively easy to substantiate my belief were it possible to perform a large stoma gastro-jejunostomy in a number of cases of gastric ulcer and to follow up the patients for some years. Fifteen years ago I advocated for gastro-jejunostomy a stoma of $3\frac{1}{2}$ to $4\frac{1}{2}$ inches in diameter,² but owing to my operations having been performed on a floating population I have been unable to trace the results of my earlier cases except in two instances. Both these patients suffered from gastric ulcers, on one I operated nineteen and on the other twelve years ago, and they have remained cured of their symptoms. Whether these results were due to the large stoma which I made or not, the number is too small from which to draw any conclusion.

From time to time I have had opportunities of watching surgeons in America and in England perform gastro-jejunostomy, but I have never seen this operation practised

except with a small stoma. Sir Berkeley Moynihan³ advocates an opening of $2\frac{1}{2}$ inches, and Messrs Rowlands and Turner⁴ recommend an opening even smaller—namely, of 2 inches in diameter.

In Singapore during the past year I have endeavoured to follow, as far as possible, my cases of large stoma gastro-jejunostomy for simple gastric and duodenal ulcer, and in this connexion I am very grateful to my colleague Dr. J. S. Webster, who has periodically examined these patients by x-rays. He finds that when a barium meal is given about half passes out practically at once through the new stoma into the jejunum, which becomes distended, and the remainder of the meal then slowly passes through the stoma, the stomach finally emptying in from one to two hours, in some cases none, in others very little, opaque meal goes through the pylorus. These examinations were conducted a week or two after operation, and again at intervals of a few weeks, the results so far have remained practically identical, and even after several months there has not been any evidence of the stoma contracting. It is interesting to note that the distension of the efferent loop of the jejunum, which is sometimes shown to be considerable appears to produce neither pain nor discomfort.

Clinically vomiting after operation is seldom encountered and as a rule the patient makes a quick and easy recovery, putting on weight and becoming able after a time, to take ordinary diet without discomfort. Vicious circle vomiting and prolapse of the jejunal mucous membrane through the large stoma into the stomach never seems to occur. Thus it would appear that one of the cardinal principles of treatment—namely, rest—is secured completely to the duodenum and considerably to the stomach.

On the other hand, I have recently come across two patients who undoubtedly had ulceration and on whom the ordinary small sized stoma gastro-jejunostomy had been done with very little relief of symptoms. One patient operated on four years ago, was never properly relieved, having recurring attacks of vomiting in spite of the most careful diet and medical treatment, this patient was x-rayed eighteen months after the operation, and the result showed a stoma through which passed very little of the opaque meal, the bulk going through the pylorus. The second patient was operated upon nine years ago for gastric ulcer soon after which he was x-rayed, the patient still has these old photographs, which clearly show that very little opaque meal then passed through the stoma. The patient was never cured, having to be readmitted into hospital from time to time with relapses, quite recently Dr. Webster x-rayed him and found that the old stoma was practically functionless, although it seemed to have been well placed in the lower part of the stomach. Dr. Webster thinks that there is now evidence of further ulceration near the pylorus. These failures, I venture to suggest, are possibly due to the stomata having been made too small.

I use the following modifications in performing a large stoma gastro-jejunostomy, which differs from the usually described operation.

1. As already stated, the stoma is at least $3\frac{1}{2}$ inches in diameter.

2. The opening in the stomach is made in its long axis or slightly oblique, whichever is the more convenient; the opening is never made in the short transverse axis of the stomach, as in this direction it would seldom be possible to make the stoma large enough.

3. The two ends only of the stomach and jejunum are held in short bladed stomach forceps, leaving the intervening portions free and unclamped. More room is thus obtained for making the stoma large. A second advantage of not clamping the stomach and intestine right across is that when these organs are incised and opened all bleeding points are seen—these are seized in artery forceps and tied with catgut. I regard this as an important detail, it adds a little time to the operation which is more than compensated I feel sure by the absence of any post-operative hæmorrhage from the stoma wounds. In other words, for complete hæmostasis reliance is not placed entirely on the tightness of the stitching. A third advantage of not clamping the stomach and jejunum right across is the

absence of bruising and injury to the mucous membranes which large clamps sometimes undoubtedly produce. Clamps may have more to do with secondary gastric and jejunal ulceration, at or close to the stoma, than is generally realized. Lately I have dispensed altogether with the stomach clamping type of forceps for holding the ends of the stomach and small bowel, using instead grooved black rubber intestine holding forceps, similar to Young's.

While I cannot ask others to share my belief that the large stoma gastro-jejunostomy will prove to be the operation of choice for simple chronic ulcers of the stomach and duodenum in the face of the numerous far more experienced surgeons whose conclusions differ from mine, I hope that my view may receive consideration.

MEDICAL, SURGICAL, OBSTETRICAL.

HAEMATURIA DURING TREATMENT WITH INSULIN

The apparent rarity of haematuria occurring in diabetic patients under insulin treatment is noted by Lawrence and Hollins in the *British Medical Journal* of June 9th (p. 977). The following case shows some points of contrast with the cases there detailed.

A boy aged 5 years was admitted to the Children's Hospital, Birmingham, on April 17th 1928. There had been no illness, except chicken pox and measles at 2 years of age, until two months before admission when he became poorly, lost weight, and had polyuria with glycosuria.

On admission he was noted to be moderately wasted and had a strong odour of acetone. The urine contained 17 grams per cent of sugar and gave a strong reaction for ketones. His blood sugar was above normal. There was no albuminuria or other abnormal urinary constituent. There were a few carious teeth, but the tonsils were small and clean. There was no evidence of infection. His progress in hospital was very good, and his diabetic state was well controlled by dieting and insulin. Apart from the first twenty-four hours in hospital when he had 20 units of insulin, he never had more than 10 units of insulin in twenty-four hours. On May 8th he was able to take an adequate diet without insulin. On May 10th his urine remained sugar free, but there was a slight positive Rothera's test. He had commenced to get up.

On May 11th at 8 a.m., whilst in bed, the boy had profuse haematuria, the urine being copious and heavily loaded with bright blood. There were no symptoms or signs otherwise. The temperature (as usual) was quite normal. There was no renal or vesical pain or tenderness. The urine was moderately acid to litmus, contained a cloud of albumin and no sugar. A slight ketosis was present. Microscopically there were very numerous red blood cells but no epithelial or blood casts. Successive specimens of urine passed during the day showed a rapid progressive diminution in the amount of blood in the urine. At 6 p.m. on the same day the specimen was practically normal to the naked eye but a haze of albumin was present together with a few red blood cells. The blood pressure was 105/60.

Two days later the urine was quite free from albumin and no abnormal elements were present microscopically. The boy went home a few weeks later and no further haematuria occurred.

The points of peculiar interest in this case are (a) that the haematuria was extreme but of very short duration, (b) the rapid return of the urine to the normal, (c) the haematuria occurred two days after the last dose of insulin, (d) there was at this time only a slight ketosis.

I do not propose to discuss the true relationship of the haematuria, but I thought perhaps the former writers and their critics might be interested in the case. Clinically the case did not appear to be nephritis. In accordance with Dr Lawrence's remarks the benign nature of the urinary abnormality is apparent also in this case.

Resident Medical Officer, Children's Hospital, Birmingham.

SOMATIC TAENIASIS

DR C. J. HILL AITKEN reported on June 2nd (p. 943) a case of somatic taeniasis which was first thought of as being malaria. A somewhat similar case occurred in St. Giles' Hospital in 1927.

A man aged 26 had been under observation in an institution as an epileptic but was sent to St. Giles' Hospital in October 1927, because he had become drowsy and dazed and the existence of some organic cerebral lesion appeared likely.

He had joined the army in 1920 and went to India where in 1925, he had an attack of malaria from which he recovered but while still in the hospital he developed epilepsy. The fits at first occurred twice a week, but later once in two months. The fits were preceded by a 'queer feeling' in the head during the convulsions and following unconsciousness he bit his tongue, but was not incontinent. The fits occurred by day and also when asleep. Sometimes he had itching in the right palm followed by twitching of the right arm before the onset of unconsciousness.

While in St. Giles' Hospital (about six weeks) there were four fits, one of which was closely observed. It lasted about five minutes, and he had sufficient warning to call a nurse. There was no loss of consciousness, the arms and legs were not involved, there was laboured breathing and profuse salivation but the mouth was not clenched. The left side of the face was twitching, sweating and flushed, the abdominal muscles on the left side were also twitching. When the facial convulsions ceased it was found that the left half of the face was paralytic and remained noticeably so for about ten minutes. The patient was able to laugh symmetrically before he could show his teeth symmetrically when asked to do so, this was demonstrated by chance and repeated as many times as laughing could be induced. There were two other left-sided facial fits, and another reported as involving both sides of the face.

When examining the head a nodule was found in the scalp over the region of the lambda, it was painless and about the size of a large pea. A similar nodule was found in the skin of the left flank, two nodules in the extensor muscles of the left forearm and another in the left gastrocnemius muscle. A nodule was excised and found to be a cyst containing hooklets.

Neurological examination gave very little help, but there was left ankle-clonus, and alternate pronation and supination of the left forearm was not so free as that of the right although the patient was left-handed. There was some papilloedema of the left eye but no abnormality of ocular movements.

Examination of the blood showed 16,000 white cells per cmm with 3 per cent of eosinophil cells. The Wassermann reaction was negative. Radiographic examination of the skull and thoracic organs was negative.

Gradually the cysts became smaller and after six weeks they could not be felt. The only treatment used was potassium iodide by the mouth.

I have to thank the medical superintendent for permission to publish this case.

Camberwell, S.E.5.

T. VIBERT PEARCE, M.B., B.S.

ACUTE PANCREATITIS FOLLOWING THE
INGESTION OF AN EXCESSIVE
AMOUNT OF ATOPHAN

In view of the recent deaths occurring after the ingestion of an excessive amount of atophan, the following case appears to be of much interest, for I do not remember having seen a case recorded where operation has been performed.

This patient developed neuralgia of a very acute type in the region of the left shoulder and arm due presumably to the fact that while passing through the tropics he had an electric fan playing on that part of the body all night. All drugs and treatment failed to relieve the neuralgia except temporarily. He was given atophan, and in despair he took a whole tubeful of ten pastilles in one day.

A few days later he informed me that the pain had passed from the left upper extremity to the pit of his stomach. The epigastrium was very tender on palpation and there was some rigidity of the recti muscles.

In the next few days his condition rapidly became worse. At a consultation it was considered that he was suffering from a mild peritonitis around a perforating type of ulcer in the lesser sac. In spite of treatment the condition continued to get rapidly worse, and I decided to perform a laparotomy. On opening the abdomen all the appearances of pancreatitis with necrosis of fat and haemorrhages in the pancreas were detected. A drainage tube was passed down to the pancreas after the peritoneum had been cut through. No calculi could be detected in any part of the pancreas. The appearance of the liver was normal. That evening the patient evinced great relief from his pain, and an enormous amount of serous fluid came away through the drainage tube.

A few days later when the patient seemed to be convalescent, he had a large haematemesis by the mouth and to all intents and purposes seemed to be dying, indeed he felt so himself, for he made his last will. Nevertheless a transfusion of blood pulled him round and he made a slow but uninterrupted recovery.

After the operation and before the haematemesis he complained of some slight pain in the left upper extremity similar in nature to the old neuralgia which disappeared completely after the haematemesis.

This man was an unusually strong and healthy individual. He had saturated himself without permission with all kinds of drugs, including atophan, and the suggestion is that severe cases which do not respond to ordinary means of treatment should be given the benefit of an exploratory operation.

Two years later a letter was received from this patient stating that he continued in good health.

M. J. PETTY, M.B., F.R.C.S.

British Hospital, Buenos Aires.

THE TREATMENT OF EARLY RODENT ULCER

Reasonably early basal-celled epitheliomata can be treated in a large number of ways with a high percentage of successes, but most methods are open to some objection. Adamson's plan of curetting, followed by a massive dose of x rays, is one of the very best, but it demands apparatus and technique beyond the compass of the general practitioner. The same applies to radium, with the additional drawback that all cases do not respond to it. Diathermy is effective but cannot safely be employed in the near neighbourhood of the eyeball. Surgical excision is good, provided that a wide margin is possible, though even then recurrence in the scar may be seen. In the neighbourhood of the eye excision may have to be on a mutilating scale, followed by plastic work, and as even then no certain promise of cure can be given, such procedures are, in my opinion, quite unjustifiable. I have in the past used many methods, but for over four years have treated all my early cases up to the size of, say, a shilling, by the following simple technique.

The rodent ulcer is ringed with novocain (2 per cent) and then firmly scraped with a sharp spoon. Only the tumour comes away and a clean raw area is left. A pencil of CO snow in a vulcanite applicator is applied with firm pressure for sixty seconds, and then a dry dressing. There is considerable oedema of the part for a day or two, but practically no pain at any time, and the ulcer heals rapidly under boric ointment.

The number of cases thus treated and observed for at least six months (the majority for much longer) is sixty-five. Of these, two showed small recurrences at the edge of the scar, where presumably an outlying nodule had escaped destruction. These recurrences were successfully treated by a repetition of the procedure. Recurrence in the depths has not so far occurred. The resulting scars are always very smooth and fine, and in the case of small rodents about the eyelids, or in the naso-labial furrow, almost invisible. The apparatus required is neither elaborate nor expensive, and the technique exceedingly simple, and there is no reason why practically every basal-celled carcinoma should not be detected and cured by the patient's family doctor. The procedure can be carried out in the consulting room, even on old people who suffer neither from shock nor pain and are perfectly fit to go home immediately afterwards.

No claim for originality in this method is made, as no doubt it or something similar is used by many other workers, but I have been moved to write this account by recent experience of recurrences following radium, x rays, and excision in other hands, and by published accounts of methods which I believe to be inferior to the one here given.

CLINICAL AND SCIENTIFIC PROCEEDINGS

ST PANCRAS DIVISION

Home Treatment of Tuberculosis by the General Practitioner

At a meeting of the St. Pancras Division held on July 10th an address on home treatment of tuberculosis by the general practitioner was delivered by Dr. W. CAMAC WILKINSON. He said that the genius of Koch had revealed the nature and origin of tuberculosis although even yet it was not easy to trace the disease to its real source or fix the time of its occurrence. To-day the paramount idea upon which the medical practitioner should deliberate and act was not that tuberculosis was an infectious disease but rather that the infectious form of tuberculosis—commonly called consumption or phthisis—could and should be prevented. Unfortunately the authorities had placed tuberculosis, even though it might not be infectious, among the infectious diseases which could be successfully combated by compulsory notification, the only justification for which lay in
